7	Adding new classes to UQpy	141

1 Overview

UQpy (Uncertainty Quantification with Python) is a general purpose Python toolbox for modeling uncertainty in the simulation of physical and mathematical systems. The code is organized as a set of modules centered around core capabilities in Uncertainty Quantification (UQ) as illustrated in Figure 1. The modules are distinct, but are designed to be easily extensible (new capabilities can be easily added and integrated into the code, see Section 7) and to easily call one another.

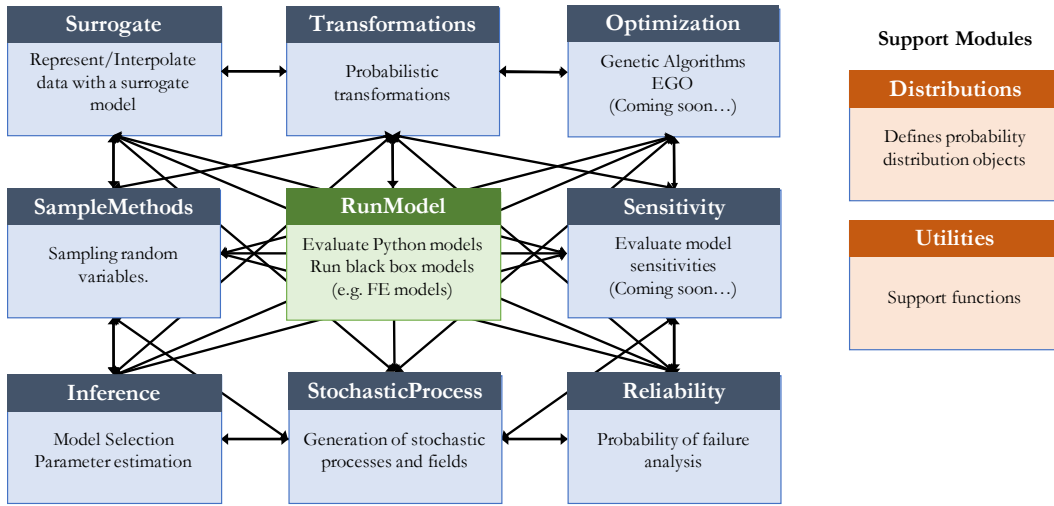

Figure 1: UQpy modules and their basic architecture.

The UQpy workflow is simple. Each module, as illustrated in Figure 1, contains a set of classes that perform various operations in UQ. A list of the current capabilities for each module is provided in Table 1. A list of expanded capabilities that are currently in development is provided in Table 2. Modules and Classes in UQpy are invoked using standard Python conventions. Because each module is organized into a set of classes, it is straightforward to add a new capability to UQpy by simply writing a new class into the appropriate module (although some care should be taken to ensure consistency in input/output naming and data type conventions). Moreover, because of its module-class structure, the various classes can easily invoke one-another and can be combined in any way the user desires. A simple example of this is that the `SubsetSimulation` class in the `Reliability` module invokes the `MCMC` class from the `SampleMethods` module.

The various classes and modules interface in a straightforward manner

Table 1: Current UQpy capabilities organized by Module and Class structure.

Module	Class	Description	Introduced
RunModel	RunModel	Execute computational model	1.0.0
Distributions	Distribution	Define a Distribution object in UQpy	2.0.0
	SubDistribution	Defines Distribution methods	2.0.0
	Copula	Defines dependence models for distributions	2.0.0
SampleMethods	MCS	Monte Carlo Sampling	1.1.0
	LHS	Latin Hypercube Sampling	1.1.0
	STS	Stratified Sampling	1.1.0
	MCMC	Markov Chain Monte Carlo	1.1.0
	IS	Importance Sampling	1.3.0
	RSS	Refined Stratified Sampling	2.0.0
	Simplex	Uniform Sampling over a simplex element	2.0.0
	Strata	Defines a Strata object for STS/RSS	1.0.0
Transformations	Correlate	Induces correlation	1.1.0
	Decorrelate	Removes correlation	1.1.0
	Nataf	Nataf transformation	1.1.0
	InvNataf	Inverse Nataf transformation	1.1.0
Surrogates	SROM	Stochastic Reduced Order Model	1.0.0
	Krig	Gaussian Process Regression (Kriging)	2.0.0
Reliability	SubsetSimulation	Subset Simulation	1.0.0
	TaylorSeries	First Order Reliability Method (FORM) Second Order Reliability Method (SORM)	2.0.0
Inference	InfoModelSelection	Information Theoretic Model Selection (AIC/BIC)	2.0.0
	BayesModelSelection	Bayesian Model Selection	2.0.0
	MLEstimation	Maximum Likelihood Parameter Estimation	2.0.0
	BayesParameterEstimation	Bayesian Parameter Estimation	2.0.0
	Model	Model Definition for Inference	2.0.0
StochasticProcess	SRM	Spectral Representation Method	2.0.0
	BSRM	Bispectral Representation Method	2.0.0
	KLE	Karhunen-Loève Expansion	2.0.0
	Translation	Translation Process	2.0.0
	InverseTranslation	Iterative Translation Approximation Method	2.0.0
Utilities	Diagnostics	Diagnostic tools for UQpy objects	2.0.0

23 with computational models of physical or mathematical systems through the
 24 **RunModel** module shown in the center of the chart in Figure 1. The **RunModel**
 25 module allows UQpy to serve not just as a useful tool for performing UQ oper-
 26 ations, but also as the driver for a complete uncertainty study - including pre-
 27 processing operations, submission and execution of computational model eval-
 28 uations, and monitoring and post-processing of results. Thus, it is amenable to
 29 performing adaptive UQ analyses. The **RunModel** module, detailed in Section
 30 5.1, is designed to interface with any user-defined third-party computational
 31 model (through Python scripts) or directly with a Python model.

Table 2: Future UQpy capabilities organized by Module and Class structure.

Module	Class	Description	Version
SampleMethods	LSS	Latinized Stratified Sampling	3.0.0
	PSS	Partially Stratified Sampling	3.0.0
	LPSS	Latinized Partially Stratified Sampling	3.0.0
	LRSS	Latinized Refined Stratified Sampling	3.0.0
	SparseGrid	Sparse Grid Cubature Sampling	3.0.0
	QMC	Quasi Monte Carlo	3.0.0
	HMC	Hamiltonian Monte Carlo	3.0.0
	Composition	Composition Sampling Method	3.0.0
Collocation	SGSC	Sparse Grid Stochastic Collocation	3.0.0
	ASGC	Adaptive Sparse Grid Collocation	3.0.0
	SCAMR	Stochastic Collocation with Adaptive Mesh Refinement	3.0.0
	SSC	Simplex Stochastic Collocation	3.0.0
	VSSC	Variance-based Simplex Stochastic Collocation	3.0.0
Surrogates	PCE	Polynomial Chaos Surrogate	3.0.0
	ANN	Artificial Neural Network Surrogate	3.0.0
	Grassmann	Grassmann Manifold Projection Surrogate	3.0.0
Reliability	TRS	Targeted Random Sampling	3.0.0
	SESS	Surrogate Enhance Stochastic Search	3.0.0
	AK-MCS	Adaptive Kriging Monte Carlo Simulation	2.1.0
Inference	KDE	Kernel Density Estimation	3.0.0
Optimization	EGO	Efficient Global Optimization	2.1.0
	GA	Genetic Algorithms	3.0.0
Sensitivity	Sobol	Sobol Indices	3.0.0
	PCESobol	Polynomial Chaos Sobol Indices	3.0.0
DimensionReduction	POD	Proper Orthogonal Decomposition	3.0.0
	DiffMap	Diffusion Maps	3.0.0

2 Installing UQpy

UQpy is written in the Python 3 programming language and requires a Python interpreter 3.5+ installed on your computer. UQpy is distributed through the Python Package Index, PyPI, and through Anaconda. Using PyPI, it can be installed using the `pip` command on the terminal as follows:

```
pip install UQpy
```

Using Anaconda, it can be installed with the `conda` command as follows:

```
conda install --channel 'SURG_JHU' uqpy
```

Upon installation, the UQpy software modules are installed in the site-packages directory of the user's Python installation. For example, within the user's

42 Python (version 3.6) installation, the installed modules can be found at:

43 `./lib/python3.6/site-packages/UQpy`

44 UQpy can be uninstalled in a similar manner using `pip`:

45 `pip uninstall UQpy`

46 or `conda`:

47 `conda uninstall UQpy`

48 2.1 Manual Installation

49 Alternatively, UQpy can be installed from GitHub directly by typing the fol-
50 lowing commands in the terminal:

51 `git clone https://github.com/SURGroup/UQpy.git`

52 `cd UQpy/`

53 `python setup.py install`

54 Direct installation from GitHub is equivalent to `pip` installation in that it
55 installs a copy of the software in the `site-packages` directory of the user's
56 Python installation.

57 UQpy can be uninstalled using `pip` as:

59 `pip uninstall UQpy`

60 or `conda`:

61 `conda uninstall UQpy`

62 2.2 Developer Installation

63 Users interested in developing new capabilities in UQpy may install it as a
64 developer. This is achieved by typing the following commands in the terminal:

65 `git clone https://github.com/SURGroup/UQpy.git`

66 `cd UQpy/`

67 python setup.py develop

68 Installing as a developer allows the user to maintain a local copy of **UQpy**
69 (located in a directory of the user's choosing) that can be edited – with changes
70 being recognized by the **UQpy** “installation”. Installing as a developer does not
71 install the software directly to site-packages as in the installation procedures
72 above. Instead, developer installation creates an ‘egg-link’ (**UQpy.egg-link**)
73 in the site-packages that directs **UQpy** calls to the user's local, editable copy of
74 the software. For more details, see the following link:

75 [http://setuptools.readthedocs.io/en/latest/setuptools.html#](http://setuptools.readthedocs.io/en/latest/setuptools.html#development-mode)

4 UQpy Modules

UQpy is currently structured according to eight core modules (see Figure 1), each centered around specific functionalities, plus two additional modules that provide supporting tools for the core modules. Additional core modules are currently under development. The complete list of modules are as follows:

Core Modules

1. **RunModel**: This module contains the `RunModel` class that allows UQpy to initiate simulations using Python or third-party computational solvers, and monitor and post-process simulation results. See Section 5.1.
2. **SampleMethods**: This module contains a set of classes to draw samples of random variables. These samples may be randomly drawn, as in Monte Carlo sampling, or they may be deterministically drawn as in sparse-grid or quasi-Monte Carlo sampling. The module also contains a number of variance reduction techniques. See Section 5.2.
3. **Inference**: This module contains a set of classes and functions to conduct probabilistic inference. The module contains methods that are based on Bayesian, frequentist, likelihood, and information theories. See Section 5.3.
4. **Reliability**: This module contains a set of classes to estimate rare event probabilities and probability of failure. See Section 5.4.
5. **Surrogates**: This module contains a set of classes for building surrogate models, meta-models, or emulators. See Section 5.5.
6. **StochasticProcess**: This module contains a set of classes and functions for simulation of stochastic processes and fields. See Section 5.6
7. **Transformations**: This module contains a set of classes for isoprobabilistic transformations. See Section 5.7.
8. **Sensitivity**: (Coming in Version 3.0.0) This module will contain a set of classes for performing global and local sensitivity analysis.
9. **Optimization**: (Coming in Version 3.0.0) This module will contain a set of classes to perform optimization for stochastic problems.

Support Modules

- 133 1. **Distributions:** This module contains a set of classes for defining prob-
134 ability distribution objects in `UQpy`. It contains several supported distri-
135 butions and associated functions (e.g. pdf, cdf, moments, random num-
136 bers, fit, inverse cdf, log_pdf) as well as allowing the user to define custom
137 distributions. See Section 6.1.
- 138 2. **Utilities:** This module contains a set of classes and functions that are
139 used in support of the other modules. See Section 6.2
- 140 The following sections detail the classes and functions in each module with
141 reference to examples that illustrate their use.

5 Core Modules

5.1 RunModel Module

The `RunModel` module is at the heart of `UPQpy`. It is a powerful module which enables `UPQpy` to drive probabilistic computational modeling. This module can interact with and call third-party software, which allows batch processing. Using the `RunModel` module only requires familiarity with Python programming language and the domain-specific knowledge of the model being evaluated. The `RunModel` module allows parallel computing such that, when processing multiple jobs, the jobs can be distributed over multiple processes or threads. In the case of cluster computing, where the jobs are performed over multiple cores on multiple compute nodes, `RunModel` is powered by GNU parallelization (see Section 5.1.5). For parallelization across a single compute node or workstation, `RunModel` employs the Python `concurrent` package when run in combination with a Python computational model, and GNU `parallel` when running a third-party software model.

5.1.1 RunModel Workflows

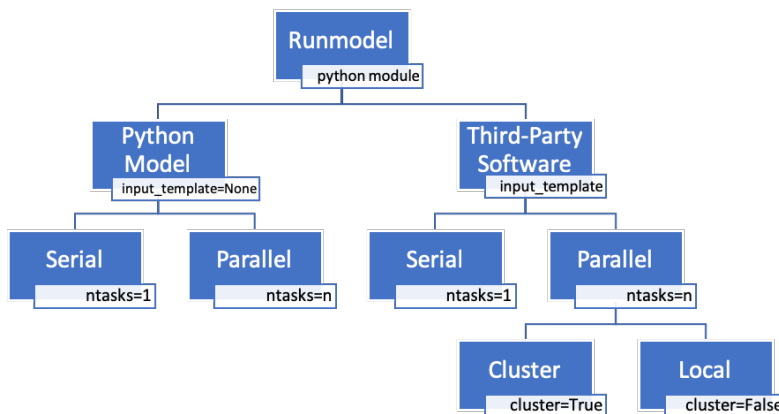

Figure 2: `RunModel` workflows and variables which trigger the different workflows.

`RunModel` class has four basic workflows delineated in two levels. At the first level, `RunModel` can be used in combination with either a Python computational model, in which case the model is imported and run directly, or in

combination with a third-party software model. When running with a third-party software model, `RunModel` interfaces with the model through text-based input files and serves as the “driver” to initiate the necessary calculations. At the second level, the jobs that are run by `RunModel` can either be executed in series or in parallel. Within the third-party model parallel execution workflow, there are two cases, which are triggered by the `cluster` variable. In the following sections we will discuss the workflows in detail.

5.1.2 `UQpy.RunModel.RunModel`

The `RunModel` module consists of a single class, also called `RunModel`, that can be imported using the following command:

```
from UQpy.RunModel import RunModel
```

The minimum required and optional attributes of the `RunModel` class depend on the desired workflow and are listed below.

The attributes of the `RunModel` class are listed below. Those required for the Python model workflow, are designated by a [1] and those that are required for the third-party model workflow are designated by a [2]:

RunModel Class Attributes					
Attribute	Input/Output	Type	Options	Default	Required
<code>samples</code>	Input	<i>list</i> or <i>ndarray</i>		None	[1], [2]
<code>model_script</code>	Input	<i>string</i>		None	[1], [2]
<code>model_object_name</code>	Input	<i>string</i>		None	
<code>input_template</code>	Input	<i>string</i>		None	[2]
<code>var_names</code>	Input	<i>list</i>		None	
<code>output_script</code>	Input	<i>string</i>		None	
<code>output_object_name</code>	Input	<i>string</i>		None	
<code>ntasks</code>	Input	<i>integer</i>		1	
<code>cores_per_task</code>	Input	<i>integer</i>		1	
<code>nodes</code>	Input	<i>integer</i>		1	
<code>resume</code>	Input	<i>bool</i>		False	
<code>verbose</code>	Input	<i>bool</i>		False	
<code>model_dir</code>	Input	<i>str</i>		None	
<code>cluster</code>	Input	<i>bool</i>		False	
<code>qoi_list</code>	Output	<i>list</i>			

Detailed Description of `RunModel` Class Attributes:

Input Attributes:

183 • **samples:**
184 Samples to be passed as inputs to the model. Samples can be passed
185 either as an *ndarray* or a *list*.

186 If an *ndarray* is passed, each row of the *ndarray* contains one set of
187 samples required for one execution of the model. (The first dimension of
188 the *ndarray* is considered to be the number of rows.)

189 If a *list* is passed, each item of the *list* contains one set of samples required
190 for one execution of the model.

191 **samples** is required for both Python and third-party software execution.

192 • **model_script**
193 The filename (with extension) of the Python script which contains com-
194 mands to execute the model. The model script must be present in the
195 current working directory from which **RunModel** is called.

196 The model script is used in different ways for the Python and third-party
197 software workflows. For further details, see Section 5.1.8.

198 • **model_object_name**
199 In the Python model workflow, **model_object_name** specifies the name
200 of the function or class within **model_script** that executes the model.
201 If there is only one function or class in the **model_script**, then it is not
202 necessary to specify **model_object_name**. If there are multiple objects
203 within the **model_script**, then **model_object_name** must be specified.

204 **model_object_name** is only used with the Python model workflow, which
205 imports the model object into the working Python environment. When
206 running a third-party software model, **RunModel** calls the **model_script**
207 from the command line and passes an input (i.e., the sample number) to
208 the **model_object**. Several approaches are possible to facilitate calling
209 the **model_script** and passing an input to the **model_object**. Refer to
210 Section 5.1.5 for an illustration using the module **Fire** to do this.

211 • **input_template:**
212 The name of the template input file which will be used to generate input
213 files for each run of a third-party model.

214 When operating **RunModel** with a third-party software model,
215 **input_template** must be specified. For details on setting up template
216 input files, see Section 5.1.8.

217 **input_template** is not used in the Python model workflow.

218 • **var_names:**
 219 A list of strings containing the names of the variables present in the
 220 template input file specified by `input_template`.

221 If an `input_template` is provided and a list of variable names is not
 222 passed, i.e. if `var_names = None`, then the default variable names x_0 ,
 223 x_1 , x_2 , ..., x_n are created and used by `RunModel`, where n is the number
 224 of variables. The number of variables is equal to the shape of the first
 225 row if `samples` is passed as an *ndarray* or the shape of the first item if
 226 `samples` is passed as a *list*.

227 For additional details on how variable names are used in the template
 228 input file to generate run files, see Section 5.1.8.

229 `var_names` is not used in the Python model workflow.

230 • **output_script:**
 231 The filename of the Python script which contains the commands to
 232 process the output from third-party software model evaluation. The
 233 `output_script` is used to return the output quantities of interest to
 234 `RunModel` for subsequent `UQpy` processing (e.g. for adaptive methods that
 235 utilize the results of previous simulations to initialize new simulations).
 236 See Section 5.1.8 for further details.

237 `output_script` is not used in the Python model workflow. In the
 238 Python model workflow, all model postprocessing is handled within
 239 `model_script`. See Section 5.1.8 for further details.

240 If, in the third-party software model workflow, `output_script = None`
 241 (the default), then `RunModel.qoi_list` is empty and postprocessing
 242 must be handled outside of `UQpy`.

243 • **output_object_name:**
 244 The name of the function or class that is used to collect the output values
 245 from third-party software model output files.

246 If the object is a class named `cls`, for example, the quantity of interest
 247 extracted from the model output must be saved as `cls.qoi`. If it is a
 248 function, it should return the output quantity of interest. If there is
 249 only one function or only one class in `output_script`, then it is not
 250 necessary to specify `output_object_name`. If there are multiple objects
 251 in `output_script`, then `output_object_name` must be specified.

252 `output_object_name` is not used in the Python model workflow.

253 • **ntasks:**
 254 Number of tasks to be run in parallel.

255 By default, **ntasks** = 1 and model evaluations are executed serially.
 256 Setting **ntasks** equal to a positive integer greater than 1 will trigger the
 257 parallel workflow.

258 RunModel uses GNU parallel to execute models which require an in-
 259 put template in parallel and the **concurrent** module to execute Python
 260 models in parallel. Further details can be found in Sections 5.1.3 and
 261 5.1.5.

262 • **cores_per_task:**
 263 Number of cores to be used by each task.

264 In cases where a third-party model runs across multiple cores in a cluster,
 265 this optional attribute allocates the necessary resources to each model
 266 evaluation. RunModel does this by using the SLURM command **srun** in
 267 addition to GNU parallel and allocating **cores_per_task** number of
 268 cores per each execution of the model. When a third-party model is run
 269 in parallel on a machine which does not use SLURM workload manager,
 270 (typically, a laptop/personal computer), GNU parallel can only specify
 271 the number of jobs to be executed in parallel and not the number of
 272 cores to be used for each job.

273 **cores_per_task** is not used in the Python model workflow.

274 • **nodes:**
 275 Number of nodes across which to distribute a single task on an HPC
 276 cluster in the third-party software model parallel workflow.

277 If a task needs to be split across more than one compute node, **nodes**
 278 must be specified. For example, the Maryland Advanced Research Com-
 279 puting Center (MARCC), an HPC shared by Johns Hopkins University
 280 and the University of Maryland, a typical compute node has 24 cores
 281 and 128 GB of memory. If each task in the parallel job requires more
 282 resources than that available on a single compute node of the cluster, it
 283 is necessary to pass in a value for **nodes** which is greater than 1.

284 **nodes** is passed as an argument to SLURM's **srun** command and should
 285 only be changed by users familiar with the **srun**. Further details regard-
 286 ing the SLURM workload manager can be found here <https://slurm.schedmd.com>
 287 **schedmd.com**

288 **nodes** is not used in the Python model workflow.

289 • **resume:**
 290 If **resume = True**, GNU parallel enables UQpy to resume execution of
 291 any model evaluations that failed to execute in the third-party software
 292 model workflow.

293 To use this feature, execute the same call to **RunModel** which failed to
 294 complete but with **resume = True**. The same set of samples must be
 295 passed to resume processing from the last successful execution of the
 296 model.

297 **resume** is not used in the Python model workflow.

298 • **verbose:**
 299 Set **verbose = True** if you want **RunModel** to print status messages to
 300 the terminal during execution. **verbose = False** by default.

301 • **model_dir:**
 302 Specifies the name of the sub-directory from which the model will be
 303 executed and within which output files will be saved.

304 **model_dir = None** by default, which results in model execution from
 305 the Python current working directory. If **model_dir** is passed a string,
 306 then a new directory is created by **RunModel** within the current directory
 307 whose name is **model_dir** appended with a timestamp. See Section 5.1.7
 308 and Figure 3 for more details.

309 • **cluster:**
 310 Set **cluster = True** if executing on an HPC cluster. Setting **cluster =**
 311 **True** enables **RunModel** to execute the model using the necessary SLURM
 312 commands. **cluster = False** by default.

313 **RunModel** is configured for HPC clusters that operate with the SLURM
 314 scheduler. In order to execute a third-party model with **RunModel** on an
 315 HPC cluster, the HPC must support SLURM commands.

316 **cluster** is not used for the Python model workflow.

317 *Output Attributes:*

318 • **qoi_list:**
 319 A list containing the output quantities of interest extracted from the
 320 model output files by **output_script**. This is a list of length equal to
 321 the number of simulations. Each item of this list contains the quantity
 322 of interest from the associated simulation.

323 5.1.3 RunModel: Python model workflow - serial execution

324 A common workflow in UQpy is when the computational model being evalu-
325 ated is written in Python. This workflow is invoked by calling `RunModel` with-
326 out specifying an `input_template` (i.e. `input_template = None`) and setting
327 `model_script` to the user-defined Python script containing the model. This
328 python model is run serially by setting `ntasks = 1`.

329 UQpy imports the `model_script` and executes the object defined by
330 `model_object_name`. The structure of the model object should be such that
331 it should accept one sample as the input. If the model object is a Class, the
332 quantity of interest must be stored as an attribute of the class `self.qoi`. If
333 the model object is a function, it must return the quantity of interest after
334 execution. In serial execution, the Python model is run with a different
335 sample in every run.

336 Samples for how the Python model may be structured are provided below.

337 Example: Model object as a class:

```
338 class ModelClass:  
339     def __init__(self, input=one_sample):  
340         Execute the model using the input and get the output  
341         self.qoi = output
```

342 Example: Model object as a function:

```
343 def model_function(input=one_sample):  
344     Execute the model using the input and get the output  
345     return output
```

346 5.1.4 RunModel: Python model workflow - parallel execution

347 The python model is executed in parallel by setting `ntasks` equal to the desired
348 number of tasks (greater than 1) to be executed concurrently. The model
349 should be defined as explained in Section 5.1.3, i.e., in the same way as for
350 the serial execution case. `RunModel` uses the python library `concurrent` for
351 parallel execution of python models, which restricts parallelization to the cores
352 available within a single node (if running on a cluster).

353 5.1.5 RunModel: Third-party software model workflow - serial execution

354 The `RunModel` class also supports running models using third-party software.

355 This workflow uses a template input file (`input_template`) to pass

356 information from **UQpy** to the third-party model, and a Python script to
357 process the outputs and collect the results after post-processing.

358

359 This workflow operates in three steps as explained in the following.

360

361 *Step 1:*

362 **UQpy** takes the file `input_template` and generates an indexed set of input
363 files, one for each set of sample values passed through the `samples` input.
364 For example, if the name of the template input file is `input.inp`, then **UQpy**
365 generates indexed input files by appending the sample number between
366 the filename and extension, as `input_1.inp`, `input_2.inp`, ... , `input_n.inp`,
367 where n is the number of sample sets in `samples`. The details of how the
368 `input_template` should be structured are discussed in Section 5.1.8. During
369 serial execution, one input file is generated, the model is executed, another
370 input file is generated, the model is executed, and so on.

371

372 *Step 2:*

373 The third-party software model is executed for each set of sample values
374 using the indexed model input file generated in Step 1 by calling the Python
375 script specified in `model_script` and passing the sample index. This can be
376 done either serially or in parallel over multiple processors (which may be
377 performed over multiple nodes of an HPC cluster). For serial execution, we
378 should set the parameter `ntasks = 1`.

379

380 *Step 3:*

381 For each simulation, the third-party model generates some set of outputs in
382 Step 2. The user-defined `output_script` is used to post-process these outputs
383 and return them to **RunModel** in a list form. This script should extract any
384 desired quantity of interest from the generated output files, again using the
385 sample index to link model outputs to their respective sample sets.

386 **UQpy** imports the `output_script` and executes the object defined by
387 `output_object_name`. The structure of the output object must be such that
388 it accepts, as input, the sample index. If the output object is a Class, the
389 quantity of interest must be stored as an attribute of the class `self.qoi`. If
390 the output object it is a function, it must return the quantity of interest after
391 execution. More details specifying the structure of `output_script` and the
392 associated output object can be found in Section 5.1.8.

393 Finally, because **UQpy** imports the `output_script` and executes it within
394 **RunModel**, the values returned by the output object are directly stored accord-
395 ing to their sample index in the **RunModel** attribute `qoi_list`.

396 5.1.6 RunModel: Third-party software model workflow - parallel execution

397 Parallel execution in RunModel module is carried out by the GNU parallel
398 library [22]. GNU parallel is essential and must be installed on the computer
399 running the model. Information regarding how to install GNU parallel is
400 provided at <https://www.gnu.org/software/parallel>. For Mac users, a
401 simple command

402 `brew cask install parallel`

403 can be used for installation. For Linux users,

404 `sudo apt-get install parallel`

405 should install the package. Parallel execution is activated in RunModel by
406 setting the parameter `ntasks>1`. The key difference in terms of the workflow
407 is listed below.

408

409 *Step 1:*

410 During parallel execution, all required input files are generated prior to model
411 execution as opposed to serial execution where input files are generated
412 individually for each run.

413

414 *Step 2:*

415 GNU parallel divides the total number of jobs into a number of chunks
416 specified by the variable `ntasks`. `ntasks` number of jobs are executed in
417 parallel and this continues until all the jobs finish executing. Note that each
418 job can be executed across multiple CPUs when `cluster = True` using the
419 SLURM workload manager. This is specified by setting `cores_per_task` and
420 `nodes` appropriately, details can be seen in Section 5.1.2. Whether in serial
421 or parallel, the sample index is used by RunModel to keep track of model
422 execution and to link the samples to their corresponding outputs. RunModel
423 achieves this by consistently naming all the input files using the sample
424 index (see Step 1) and passing the sample index into `model_script`. More
425 details on the precise structure of `model_script` are discussed in Section 5.1.8.

426

427 *Step 3:*

428 No key difference between the serial and parallel workflow in terms of output
429 processing. Output processing in the parallel case is done after all the runs
430 are completed, whereas in the serial case it is done after every run.

431 5.1.7 Directory structure during model evaluation

432 To execute `RunModel`, the directory from where `RunModel` is called must
433 contain the necessary files (i.e. `model_script`, `input_template`, and
434 `output_script`) along with any other files required for model evaluation.
435 These may include, among other things, compiled executable files for
436 third-party software that runs locally. There is an option to specify a
437 `model_dir` as an input to `RunModel`. If a `model_dir` is specified, `RunModel`
438 creates a new directory whose name is given by appending a timestamp
439 corresponding to the time of executing the model to `model_dir`. All the files
440 in the working directory are copied to the newly created model directory as
441 illustrated in Figure 3 and this directory becomes the working directory for
442 executing the model. If a `model_dir` is not specified, the current directory is
443 the working directory for model execution.

444 To avoid cluttering the working directory with outputs, `RunModel` creates
445 a directory for each execution of the model and saves the output generated
446 during the model execution within the corresponding directory. `RunModel`
447 generates the directory name for the sample as `run_n_timestamp`, where `n` goes
448 from 0 to `number of samples-1`, and `timestamp` corresponds to the time at
449 the beginning of the first simulation of the parallel job. See Figure 4 for an
450 illustration.

451 Within the directory for each run, `RunModel` creates a new directory
452 `InputFiles` and deposits the input files generated in Step 1 above into this
453 directory. The user's `model_script` must retrieve the relevant input file
454 during the model execution. During model execution, `RunModel` first copies
455 all the files in the working directory to the directory for each sample, executes
456 the model, and then deletes all the files copied into this directory from the
457 working directory. Any output generated either during model execution or
458 during output processing remains in this directory along with the `InputFiles`
459 directory. See Figure 5 for an illustration.

460 5.1.8 Files and scripts used by `RunModel`

461 As discussed in the sections above and illustrated in the examples, the
462 `RunModel` class utilizes a python script to execute the computational model
463 (`model_script`), a python script to extract the output (`output_script`) and
464 a template input file (`input_template`). This section is intended to provide a
465 closer look at each of these files, their structure, and when/if they are required.

466

467 `input_template:`

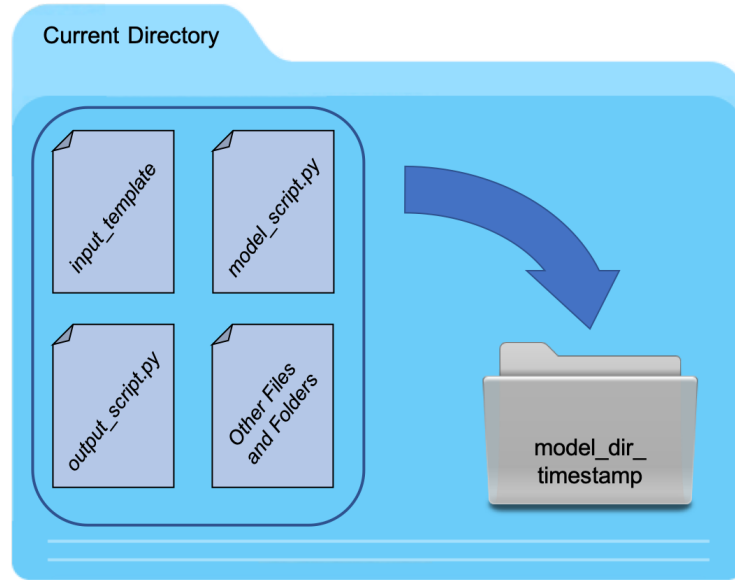

Figure 3: If a `model_dir` is specified, `RunModel` first copies all files into a subdirectory of the working directory called `model_dir_timestamp` where all computations will be performed and this directory becomes the working directory. If `model_dir` is not specified, the current directory is the working directory.

- `input_template` is a user-defined file that is used only when executing a third-party software model with `RunModel`. As the name implies, `input_template` serves as a template of the model input file from which individual model input files will be generated for each model evaluation. The model input file is typically an ASCII text-based file that defines all parameters, geometry, material, properties, etc. of the computational model. For each individual model evaluation, `RunModel` will modify this template through place-holder variables following a `UQpy` specific convention. This convention is described herein. The place-holder variables are replaced by `RunModel` with numerical values from the `samples` passed as input to `RunModel`.

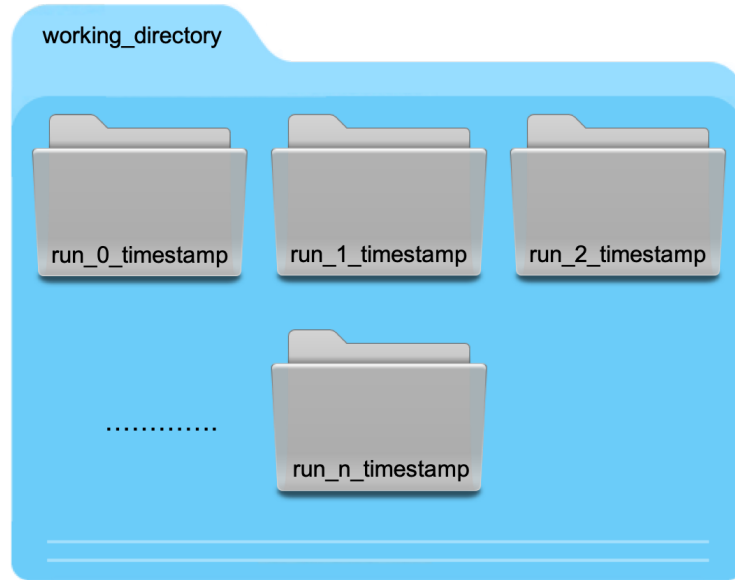

Figure 4: Within the working directory, `RunModel` creates folders, one for each sample input to the model. Each folder contains the input and output corresponding to that model run.

- Place-holders are defined by using `< >` around the variable name within the template input file. The variable names are specified within `RunModel` using the `var_names` input. `RunModel` scans the text within the input template looking for place-holders with each variable name and places the values in the appropriate location in the model input file. For example, if the user passes `var_names = ['var1']` and `samples = [[5.2], [3.9], [4.4]]`, `RunModel` will generate three input files (one for each sample). In the first input file, the value of 5.2 replaces the place-holder `<var1>` wherever it appears in the the template input file. In the second and third input files, `<var1>` is replaced by 3.9 and 4.4 respectively.
- As previously stated, if `var_names = None`, `RunModel` assigns variable names as $x_0, x_1, x_2, \dots, x_n$.

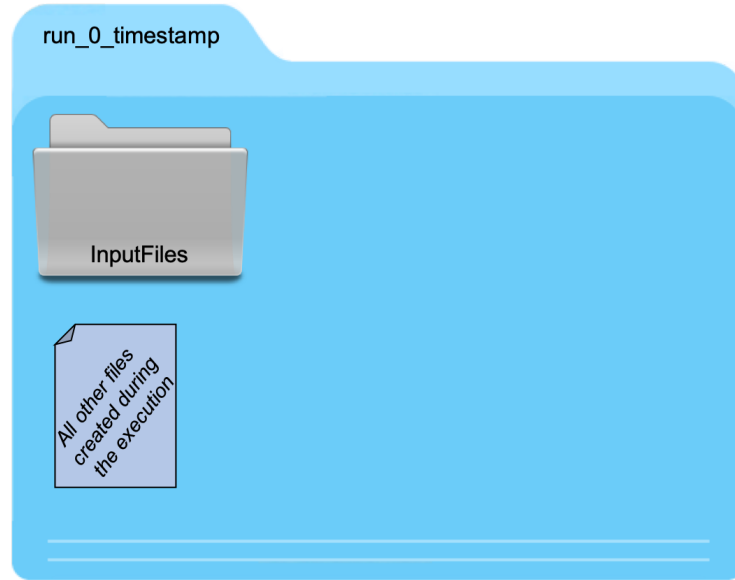

Figure 5: Within each directory corresponding to one sample, **RunModel** creates a folder called **InputFiles** which contains the input file generated using that sample. All outputs generated during the model execution using that sample are also stored in this directory.

Standard python indexing is supported when using the place-holders i.e., if **var1** is an array, then it is possible to specify, for example, **<var1[0][2]>**, which will then use the corresponding component of **var1** at that location. If **var1** is an array and when no specific component of **var1** is specified within the place-holders, i.e. if in the input template, only **<var1>** is used, then the entire contents of **var1** are written in a comma-separated format at that location in the input file.

- When **RunModel** is executed, it generates one input file for each row / item of **samples** using the template input file. The names of the input files are built by appending an underscore and the sample index between the filename and the extension of the template input file. These input files are moved to a subdirectory, named **InputFiles** of the current

504 working directory.

- 505 • An example of the usage of a template input follows for a simple Matlab
506 model. In this example, three input files are generated for three samples
507 of a single variable.

508 The template input file is given as:

509	<pre>matlab_model.m x = <var1>; y = x^2; fid = fopen('y.txt','w'); fprintf(fid, '%d', y); fclose(fid);</pre>
-----	--

510

511 RunModel is called as follows:

```
512       x = RunModel(samples = [[1.1], [2.5], [3.3]], model_script
513       = 'matlab_model_script.py', input_template = 'matlab_model.m',
514       var_names = ['var1'], output_script = 'output.py',
515       output_object_name = 'postprocess', ntasks = 1)
```

516 When RunModel is executed, it then builds three input files as follows:

517

518	<pre>matlab_model_1.m x = 1.1; y = x^2; fid = fopen('y.txt','w'); fprintf(fid, '%d', y); fclose(fid);</pre>
-----	---

519

520	<pre>matlab_model_2.m x = 2.5; y = x^2; fid = fopen('y.txt','w'); fprintf(fid, '%d', y); fclose(fid);</pre>
-----	---

521

```
matlab_model_3.m
x = 3.3;
y = x^2;
fid = fopen('y.txt','w');
fprintf(fid, '%d', y);
fclose(fid);
```

522

523

524 These three files serve as input to the model that is evaluated by
525 `model_script`, which is discussed next.

526 `model_script`:

527 `model_script` is the user-defined Python script that runs the computational
528 model. It can be employed in two different ways depending on the type of
529 model being executed.

530 • **Python Model:** The `model_script` should have defined within it an
531 object (either a class object or a function object), specified in `RunModel`
532 by `model_object_name`, which contains the computational model itself.
533 In such a case, the `samples` passed to `RunModel` are passed as inputs to
534 the model object. Refer to 5.1.3 for the structure of `model_script` in
535 this case.

536 • **Third-party Software Model:** When running a third-party model,
537 `RunModel` does not import `model_script`. Instead, `RunModel` calls the
538 model script through the command line as

539 `python3 model_script(sample_index)`

540 using the Python `fire` module. Notice the only variable passed into
541 `model_script` is the sample index. This is because the samples are being
542 passed through the input files. For example, if the model object is passed
543 the sample index n , it should then execute the model using the input file
544 whose name is `input_n.inp`, where `input_template = input.inp`.

545 An example of the the `model_script` corresponding to execution of a
546 Matlab model with `input_template = matlab_model.m`, as illustrated
547 in the `input_template` example, is given below.

548

```

matlab_model_script.py
import os
import fire

if __name__ == '__main__':
    fire.Fire(model)

def model(sample_index):
    # Copy the input file into the cwd
    command1 = "cp ./InputFiles/matlab_model_"
        + str(index + 1) + ".m ."
    # Run the model
    command2 = "matlab -nosplash -nojvm -nodisplay
        -nodesktop -r 'run matlab_model_"
        + str(sample_index + 1) + ".m; exit'"
    # Rename the output file
    command3 = "mv y.txt y_" + str(sample_index + 1)
        + ".txt"
    os.system(command1)
    os.system(command2)
    os.system(command3)

```

In `model_script` file, it is necessary to build the executable commands into a function (here called `model`) so that the sample index can be passed into the script – allowing the script to recognize which input file to use. Because the executable commands must be built into a function, it is necessary to call this function using the Python `fire` module as illustrated in the first two lines of `matlab_model_script.py`.

Again, `RunModel` is called as follows:

```

x = RunModel(samples = [[1.1], [2.5], [3.3]], model_script
= 'matlab_model_script.py', input_template = 'matlab_model.m',
var_names = ['var1'], output_script = 'output.py',
output_object_name = 'postprocess', ntasks = 1)

```

Also notice that the model script must index the name of the output file for subsequent postprocessing through the `output_script` as discussed next.

`output_script:`

566 • `output_script` is an optional user-defined Python script for post-
567 processing model output. Specifically, it is used to extract user-specified
568 quantities of interest from third-party model output files and return
569 them to `RunModel`. `output_script` is used only when using `RunModel`
570 with a third-party software model.

571 • `UQpy` imports the `output_script` and executes the object defined by
572 `output_object_name`. The structure of the output object should be such
573 that it accepts only the sample index as the input. If the model object
574 is a Class, the quantity of interest must be stored as an attribute of the
575 class `self.qoi`. If it is a function, it must return the quantity of interest
576 after execution.

577 In summary, if the output object is a class, it should be structured as
578 follows:

```
579 class OutputClass:  
580     def __init__(self, input=sample_index):  
581         Post-process the output files corresponding the the sample number  
582         and extract the quantity of interest.  
583         self.qoi = output
```

584 or if it is a function, it should be structured as follows:

```
585 def output_function(input=sample_index):  
586     Post-process the output files corresponding the the sample number  
587     and extract the quantity of interest.  
588     return output
```

589 In keeping with the Matlab example illustrated for the `input_template`
590 and `model_script`, an example `output_script` is given as follows:

591

output.py
<pre>def postprocess(sample_index): x = np.loadtxt("y_%d.txt" % (sample_index + 1)) return x</pre>

592

593

594 **Executable Software:**

595 Often, the working directory will contain an executable software program.
596 This is the case when the software does not lie in the user's path.

597 **5.1.9 Examples & Template Files:**

598 Examples illustrating the use of `RunModel` are provided in the following
599 `Jupyter` notebooks.

600 • `Matlab_Model_Example.ipynb`:

601 In this example, a small set of one dimensional random samples are
602 drawn from a standard Normal distribution using the `MCS` class. Matlab
603 is called to return the square of the random variable using the `RunModel`
604 class.

605 • `Python_Model_Example.ipynb`:

606 In this example, a set of 10,000 three-dimensional random sam-
607 ples are drawn from a standard Normal distribution using the
608 `MCS` class. Two Python models, `python_model_class.py` and
609 `python_model_function.py`, are called to sum each of the 10,000
610 random samples. The first model structures the Python model as a
611 class and the second model structures the Python model as a function.
612 Both models are run serially and in parallel.

613 A number of template scripts for commonly used third-party software ap-
614 plications are currently under development. These templates should not be
615 considered as fully-functional software models (as is the case with the pro-
616 vided examples). Instead, they are meant to provide an initial starting point
617 for users interested in linking `UQpy` with common software.

618 • Matlab

619 See `dummy_model.m` in the above mentioned Matlab model example.

620 • Abaqus

621 A sample Abaqus input file can be found in the example directory at:
622 `UQpy/example/RunModel/Abaqus_Model_Example/single_element.inp`

623 • LS-DYNA

633 5.2 SampleMethods Module

634 The `SampleMethods` module consists of classes to draw samples of random
635 variables. It is imported in a python script using the following command:

```
636 from UQpy import SampleMethods
```

637 The `SampleMethods` module has the following classes, each corresponding to
638 a different sampling method:

Class	Method
MCS	Monte Carlo Sampling
LHS	Latin Hypercube Sampling
STS	Stratified Sampling
MCMC	Markov Chain Monte Carlo
IS	Importance sampling
RSS	Refined Stratified Sampling
Simplex	Uniform Sampling on a Simplex

640 Each class can be imported individually into a python script. For example,
641 the `MCMC` class can be imported to a script using the following command:

```
642 from UQpy.SampleMethods import MCMC
```

643 The following subsections describe each class, their respective inputs and at-
644 tributes, and their use.

5.2.1 UQpy.SampleMethods.MCS

Theory

Monte Carlo sampling (MCS) generates independent random draws from a specified probability distribution or distributions. The MCS class utilizes the `Distributions` class to define probability distributions (see Section 6.1). Using the `Distributions` class, the user may specify an inbuilt parametric distribution (Table 3) or a custom distribution as outlined in Section 6.1.

The advantage of using the `MCS` class for UQpy operations, as opposed to simply generating samples with the `scipy.stats` package, is that it builds an object containing the samples, their distributions, parameters, and variable names for integration with other UQpy modules.

If MCS is used to generate multi-variate random vectors, the components of the vector will be independent and will therefore follow a product distribution. To induce correlation between components, use the `Transformations.Correlate` class as described in Section 5.7.1.

Using the MCS Class

The MCS class is imported using the following command:

```
from UQpy.SampleMethods import MCS
```

The attributes of the MCS class are listed below:

MCS Class Attributes					
Attribute	Input/Output	Type	Options	Default	Required
<code>dist_name</code>	Input	<i>string</i> <i>string list</i>	See <code>Distributions</code> Module	None	★
<code>dist_params</code>	Input	<i>ndarray</i> <i>list</i>	See <code>Distributions</code> Module	None	★
<code>nsamples</code>	Input	<i>integer</i>		None	★
<code>var_names</code>	Input	<i>string</i> <i>string list</i>		None	
<code>verbose</code>	Input	<i>boolean</i>		False	
<code>samples</code>	Input	<i>ndarray</i>			

Detailed Description of MCS Class Attributes:

Input Attributes:

- `dist_name`:
Defines the name of the distribution for each random variable.
`dist_name` may be a string or a list of strings.

673 If `dist_name[i]` is a string, the distribution is matched with one of the
674 available distributions in the `Distributions` module (see Sec. 6.1) or
675 the user-defined custom distribution is called (again see Sec. 6.1).
676 `dist_name` must be specified. There is no default value.

- 677 • **dist_params:**
678 Specifies the parameters for each distribution in `dist_name`.
679 Each set of parameters is defined as a numpy array. `dist_params` is a
680 list of arrays, with each item in the list corresponding to the associated
681 random variable.
682 `dist_params` must be specified. There is no default value.
- 683 • **nsamples:**
684 Specifies the number of samples to be generated as an integer.
685 `nsamples` must be specified. There is no default value.
- 686 • **var_names:**
687 Specifies the names of the random variables. Variable names are used as
688 place-holders within input files for analyses driven by `RunModel`.
689 `var_names` is optional and should contain a list of strings of the same
690 length as the number of random variables.
691 `var_names` has no default value.
- 692 • **verbose:**
693 Specifies whether text is written to the terminal declaring the status of
694 the MCS evaluation.
695 `verbose` is of boolean type with default `verbose = False`.

696 *Output Attributes:*

- 697 • **samples:**
698 A numpy array of dimension `nsamples × n`, where `n` is the number of
699 random variables, containing the generated random samples following
700 the specified distribution.

701 **Examples:**
702 Two examples illustrating the use of the `MCS` class are provided in the following
703 Jupyter notebooks.

- 704 • MCS_Example1.ipynb:
705 In this example, 1000 2-dimensional samples are drawn from a standard
706 normal distribution.
- 707 • MCS_Example2.ipynb:
708 In this example, 1000 2-dimensional samples are drawn from a custom
709 distribution (defined through custom_dist.py).

710 5.2.2 UQpy.SampleMethods.LHS

711 Theory

712 Latin hypercube sampling (LHS) [13] belongs to the family of stratified
 713 sampling techniques [20] and has the advantage that the samples generated
 714 are uniformly distributed over each marginal distribution. LHS is performed
 715 by dividing the the range of each random variable into N bins with equal
 716 probability mass, where N is the required number of samples, generating one
 717 sample per bin, and then randomly pairing the samples. Variance reduction
 718 properties of LHS are discussed in [21].

719

720 Using the LHS Class

721 LHS is a class for Latin hypercube sampling. The LHS class is imported using
 722 the following command:

```
723 from UQpy.SampleMethods import LHS
```

724 The attributes of the LHS class are listed below:

LHS Class Attributes					
Attribute	Input/Output	Type	Options	Default	Required
dist_name	Input	<i>string</i> <i>string list</i>	See Distributions	None	★
dist_params	Input	<i>ndarray list</i>		None	★
lhs_criterion	Input	<i>string</i>	'random' 'centered' 'maximin' 'correlate'	'random'	
lhs_metric	Input	<i>string</i>	'braycurtis', 'canberra', 'chebyshev' 'cityblock', 'correlation', 'cosine' 'dice', 'euclidean', 'hamming' 'jaccard', 'kulsinski', 'mahalanobis' 'matching', 'minkowski', 'rogerstanimoto' 'russellrao', 'seuclidean', 'sokalmichener' 'sokalsneath', 'sqeuclidean', 'yule'	'euclidean'	
lhs_iter	Input	<i>integer</i>		100	
nsamples	Input	<i>integer</i>		None	★
samplesU01	Output	<i>ndarray</i>			
samples	Output	<i>ndarray</i>			

726 Detailed Description of LHS Class Attributes:

727

728 *Input Attributes:*

- 729 • **dist_name:**

730 Defines the distributions for each random variable.

731 **dist_name** may be a string or a list of strings.

732 The string `dist_name[i]` is matched with with one of the available func-
733 tions in the `Distributions` module (see Sec. 6.1, Table 3) or the custom
734 distribution (again see Sec. 6.1).

735 `dist_name` must be specified. There is no default value.

- 736 • **dist_params:**
737 Specifies the parameters for each distribution in `dist_name`.
738 Each set of parameters is defined as a numpy array. `dist_params` is a
739 list of arrays, with each item in the list corresponding to the associated
740 random variable.
741 Refer to the `Distributions` module in Section 6.1.
742 `dist_params` must be specified. There is no default value.
- 743 • **lhs_criterion:**
744 Design criterion for the Latin hypercube samples. The different choices
745 available are given below:
 - 746 – ‘random’: Samples are drawn randomly in the Latin hypercube
747 strata.
 - 748 – ‘centered’: Samples are centered in the Latin hypercube strata.
 - 749 – ‘maximin’: The minimum distance between the sample points is
750 maximized.
 - 751 – ‘correlate’: The correlation among the sample points is minimized.
752 Default is ‘random’.
- 753 • **lhs_metric:**
754 Specifies the distance metric to be used in the case of ‘maximin’ criterion.
755 The choices are the available distance metrics in `scipy`.
756 Only required in the case of `lhs_criterion = ‘maximin’`.
757 Default is ‘euclidean’.
- 758 • **lhs_iter:**
759 Specifies the number of iterations to be run for deciding the design in the
760 case of `lhs_criterion = ‘maximin’` and `lhs_criterion = ‘correlate’`.
- 761 • **nsamples:**
762 Specifies the number of samples to be generated.
763 `nsamples` must be specified. There is no default value.

764 • **var_names:**
765 Specifies the names of the random variables. Variable names are used as
766 place-holders within input files for analyses driven by `RunModel`.
767 **var_names** is optional and should contain a list of strings of the same
768 length as the number of random variables.
769 **var_names** has no default value.

770 • **verbose:**
771 Specifies whether text is written to the terminal declaring the status of
772 the MCS evaluation.
773 **verbose** is of boolean type with default `verbose = False`.

774 *Output Attributes:*

775 • **samplesU01:**
776 A numpy array of dimension `nsamples × dimension` containing the sam-
777 ples generated uniformly on the hypercube $[0, 1]^{\text{dimension}}$.

778 • **samples:**
779 A numpy array of dimension `nsamples × dimension` containing the sam-
780 ples following the specified distribution.

781 **Examples:**
782 An example illustrating the use of the `LHS` class is provided in the following
783 Jupyter notebook.

784 • **LHS.ipynb:**
785 In this example, 5 2-dimensional samples are drawn using Latin hyper-
786 cube sampling with different `lhs_criterion` to illustrate its use.

787 5.2.3 UQpy.SampleMethods.MCMC

788 Theory

789 The goal of Markov Chain Monte Carlo is to draw samples from some proba-
 790 bility distribution $p(x) = \frac{\tilde{p}(x)}{Z}$, where $\tilde{p}(x)$ is known but Z is hard to compute
 791 (this will often be the case when using Bayes' theorem for instance). In order
 792 to do this, the theory of a Markov chain, a stochastic model that describes
 793 a sequence of states in which the probability of a state depends only on the
 794 previous state, is combined with a Monte Carlo simulation method. More
 795 specifically, a Markov Chain is built and sampled from whose stationary dis-
 796 tribution is the target distribution $p(x)$. The reader is referred to e.g. [7]
 797 for more theory about MCMC methods. The Metropolis-Hastings (MH) algo-
 798 rithm goes as follows:

- 799 • initialize with a seed sample x_0
- 800 • walk the chain: for $k = 0, \dots$ do:
 - 801 – sample candidate $x^* \sim Q(\cdot|x_k)$ for a given Markov transition prob-
 - 802 ability Q
 - accept candidate (set $x_{k+1} = x^*$) with probability

$$\alpha(x^*|x_k) := \min \left\{ \frac{\tilde{p}(x^*)}{\tilde{p}(x)} \cdot \frac{Q(x|x^*)}{Q(x^*|x)}, 1 \right\}$$

803 otherwise propagate last sample $x_{k+1} = x_k$

804 UQpy supports MH along with more advanced algorithms such as Modified
 805 Metropolis Hastings (MMH, [3]) and the Affine invariant ensemble sampler
 806 ([9]). The transition probability Q is chosen by the user (see inputs
 807 `pdf_proposal_type` and `pdf_proposal_scale`), and careful attention must
 808 be given to that choice as it plays a major role in the accuracy and efficiency
 809 of the algorithm. Figure 6 shows samples accepted (blue) and rejected
 810 (red) when trying to sample from a 2d Gaussian distribution using MH, for
 811 different scale parameters of the proposal distribution. If the scale is too
 812 small, the space is not well explored; if the scale is too large, many candidate
 813 samples will be rejected, yielding a very inefficient algorithm. As a rule of
 814 thumb, an acceptance ratio of 10%-50% could be targeted (see `Diagnostics`
 815 in the `Utilities` module).

816 Finally, samples from the target distribution will be generated only
 817 when the chain has converged to its stationary distribution, after a so-called
 818 burn-in period. Thus the user would often reject the first few samples (see

Figure 6: Sampling from a 2d Gaussian pdf using the MH algorithm and various scale parameters of the transition probability Q : in blue are the accepted draws from the Markov chain, in red the draws that were rejected.

819 input `burn`). Also, the chain yields correlated samples; thus to obtain i.i.d.
 820 samples from the target distribution, the user should keep only one out of
 821 `jump` samples (see input `jump`). This means that the code will perform in
 822 total `burn+jump*nsamples` evaluations of the target pdf to yield `nsamples`
 823 i.i.d. samples from the target distribution (for the MH algorithm).

824

825 Using the MCMC class

826 In UQpy, the MCMC class is imported using the following command:

```
827 from UQpy.SampleMethods import MCMC
```

828 The attributes of the MCMC class are listed below:

MCMC Class Attributes					
Attribute	Input/Output	Type	Options	Default	Required
dimension	Input	integer		dimension = 1	*
algorithm	Input	string	'MH' 'MMH' 'Stretch'	'MH'	
pdf_proposal_type	Input	string	'Normal' 'Uniform'	'Normal'	
pdf_proposal_scale	Input	float float list		if algorithm = 'MMH' or 'MH': pdf_proposal_scale = [1, 1, ..., 1] if algorithm = 'Stretch': pdf_proposal_scale = 2	
pdf_target ¹	Input	function string			*
log_pdf_target ¹	Input	function		None	*
pdf_target_params	Input	float float list		None	
pdf_target_copula	Input	str		None	
pdf_target_copula_params	Input	float float list		None	
pdf_target_type	Input	string	'marginal_pdf' 'joint_pdf'	only used if algorithm = 'MMH'	
jump	Input	integer		1	
nsamples	Input	integer		None	*
seed	Input	ndarray ndarray list		array(0, 0, ..., 0) size = 1 × dimension	
nburn	Input	integer		0	
verbose	Input	boolean		False	
samples	Output	ndarray			
accept_ratio	Output	float			

Detailed Description of MCMC Class Attributes:

Input Attributes:

- **dimension:**
A scalar integer value defining the dimension of the random variables.
- **algorithm:**
Specifies the algorithm used to generate samples. **UQpy** currently supports three commonly used algorithms.
 - 'MH':
Metropolis-Hastings algorithm. For a description of the algorithm, see [14, 12, 3].
 - 'MMH':
Component-wise modified Metropolis-Hastings algorithm. For a description of the algorithm, see [3].
 - 'Stretch':
Affine invariant ensemble sampler employing “stretch” moves. For a description of the algorithm, see [9].

¹One of `pdf_target` or `log_pdf_target` is required.

847 • `pdf_proposal_type`:
 848 Type of proposal density function. This option is only invoked when
 849 `algorithm = 'MH'` or `'MMH'`. `UQpy` currently supports two types of
 850 proposal densities:

851 – ‘Normal’ (default):
 852 The proposal density is specified as a normal distribution with mean
 853 value equal to the current state of the Markov Chain and standard
 854 deviation specified by `pdf_proposal_scale`. That is, a new candi-
 855 date sample is generated as
 856 $x_{i+1} \sim N(x_i, \text{pdf_proposal_scale})$.

857 – ‘Uniform’:
 858 The proposal density is specified as a uniform distribution cen-
 859 tered at the current state of the Markov Chain with width equal to
 860 `pdf_proposal_scale`. That is, a new candidate sample is generated
 861 as
 862 $x_{i+1} \sim U(x_i - \text{pdf_proposal_scale}/2, x_i + \text{pdf_proposal_scale}/2)$.

863 When `dimension > 1`, `pdf_proposal_type` may be specified as a string
 864 or a list of strings assigned to each dimension. When `pdf_proposal_type`
 865 is specified as a string, the same proposal type is specified for all dimen-
 866 sions.

867 • `pdf_proposal_scale`:
 868 Sets the scale of the proposal probability density. The scale
 869 of the proposal density depends on both the MCMC algorithm
 870 employed (`algorithm`) and the type of proposal density specified
 871 (`pdf_proposal_type`).

872 – For `algorithm = 'MH'` or `'MMH'`, this defines either the standard
 873 deviation of a normal proposal density or the width of a uniform
 874 density. See `pdf_proposal_type` above.

875 – For `algorithm = 'Stretch'`, this sets the scale of the stretch density
 876 $g(z) = \frac{1}{\sqrt{z}}, \sim z \in [1/\text{pdf_proposal_scale}, \text{pdf_proposal_scale}]$.
 877 See [9].

878 When `dimension > 1`, `pdf_proposal_scale` may be specified as
 879 a scalar or a list of values assigned to each dimension. When
 880 `pdf_proposal_scale` is specified as a scalar, the same scale is specified
 881 for all dimensions.

882 • `pdf_target_type`:
883 [Use only with `algorithm = 'MMH'`]
884 MCMC algorithms use acceptance-rejection based on a ratio of the target
885 probability densities between the current state and the proposed state. In
886 the 'MH' algorithm and the 'Stretch' algorithm, the ratio of probabilities
887 is computed using the target joint pdf. For the 'MMH' algorithm with
888 independent random variables, acceptance/rejection can be computed
889 based on the ratio of the marginals for each dimension. This variable
890 specifies whether to use a ratio of target joint pdf's or a ratio of target
891 marginal pdf's in the acceptance-rejection step for each dimension of the
892 'MMH' algorithm. This option is not used for the 'MH' and 'Stretch'
893 algorithms.

- 894 – 'joint_pdf':
895 Compute the acceptance-rejection using the ratio of the target joint
896 pdf's. [Always use when random variables are dependent.]
- 897 – 'marginal_pdf':
898 Compute the acceptance-rejection using the ratio of target marginal
899 pdf's in each dimension. [Only use when random variables are in-
900 dependent.]

901 • `log_pdf_target`:
902 Specifies the density function p (or equivalently the unscaled \tilde{p}), from
903 which to draw MCMC samples `log_pdf_target` can be either:

- 904 – a function (or list of functions for marginals):
905 The easiest way to define `log_pdf_target` is to pass it as a function,
906 or `log_pdf` method of a `Distribution` class instance. This function
907 must take as input parameter at least one input \mathbf{x} , the point where
908 to evaluate the pdf, and can additionally take as input parameters
909 `params`, `copula_params`.
- 910 – a string (or list of strings for marginals):
911 In this case, a `Distribution` instance will be created using
912 `p=Distribution(dist_name=log_pdf_target)`, and its `log_pdf`
913 method will be called to evaluate $\log(\tilde{p}(x))$. The distribution can
914 also accept a copula. If the built distribution `p` does not have a
915 `log_pdf` method, an error is raised.

916 Alternatively to specifying `log_pdf_target`, the user can specify
917 `pdf_target`, see following item. However, for stability reasons (pdf

values can become very small for unlikely draws), the algorithm always uses log pdfs instead of pdfs, thus, if possible, providing a log_pdf function instead of a pdf is preferred. Figure 7 shows how the code checks the existence of a log_pdf or pdf callable that is used to evaluate $\log(\tilde{p}(x))$.

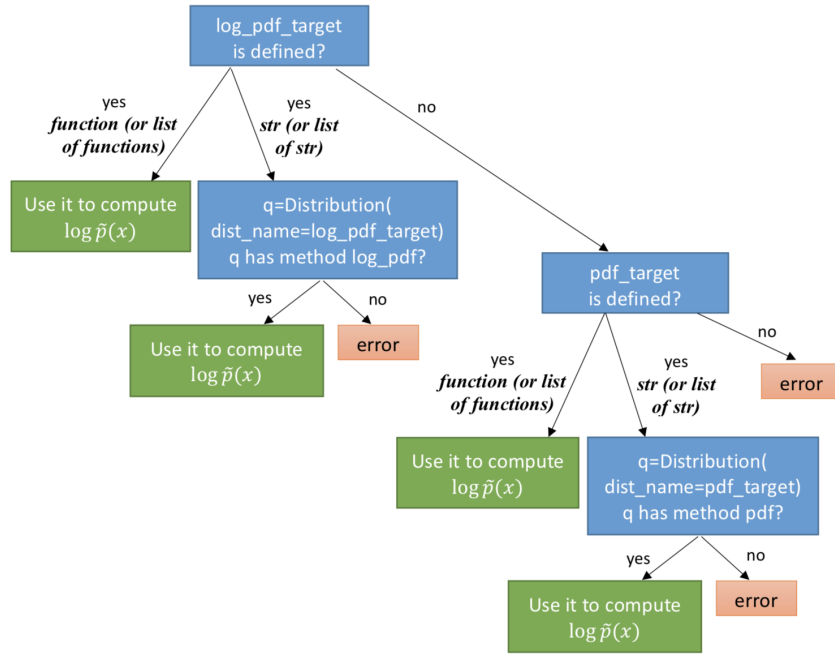

Figure 7: Diagram explaining how the code checks for the existence of the target distribution, used to evaluate $\log(\tilde{p}(x))$.

- **pdf_target:**
Specifies the target probability density function from which to draw MCMC samples, alternative to defining `log_pdf_target`. `pdf_target` can be either:
 - a function (or list of functions for marginals):
The easiest way to define `pdf_target` is to pass it as a function, or `pdf` method of a `Distribution` class instance. This function must take as input parameter at least one input `x`, the point where to evaluate the pdf, and can additionally take as input parameters `params`, `copula_params`.
 - a string (or list of strings for marginals):
In this case, a `Distribution` instance will be created using

935 `p=Distribution(dist_name=pdf_target)`, and its `pdf` method
936 will be called to evaluate $\log(\tilde{p}(x))$. The distribution can also
937 accept a copula. If the built distribution `p` does not have a `log_pdf`
938 method, an error is raised.

939 When `dimension > 1` and `pdf_target_type = 'marginal_pdf'`,
940 `pdf_target` may be specified as a string/function or a list of
941 strings/functions assigned to each dimension. When specified as a
942 string/function, the same marginal pdf is specified for all dimensions.

- 943 • **pdf_target_params:**
944 Parameters of the target pdf to be passed as arguments to the function
945 defined by `pdf_target`, `log_pdf_target`.
- 946 • **pdf_target_copula:**
947 Copula name of the target pdf if it exists. Used only if `pdf_target`,
948 `log_pdf_target` are defined using strings/list of strings.
- 949 • **pdf_target_copula_params:**
950 Parameters of the copula of the target pdf to be passed as arguments to
951 the function defined by `pdf_target`, `log_pdf_target`.
- 952 • **jump**
953 Specifies the number of samples between accepted states of the Markov
954 chain. Setting `jump = 1` corresponds to accepting every state. Setting
955 `jump = n` corresponds to skipping $n - 1$ states between accepted states
956 of the chain.
- 957 • **nburn**
958 Specifies the number of samples at the start of the chain to be discarded
959 as “burn-in.” This option is only applicable for `algorithm='MMH'` and
960 ‘MH’.
- 961 • **nsamples**
962 Specifies the number of samples to be generated (not including the dis-
963 carded burn-in states nor the skipped states of the chain).
964 `nsamples` must be specified. There is no default value.
- 965 • **seed**
966 Specifies the initial state of the Markov chain.
- 967

968 For `algorithm = 'MMH'` or `'MH'`, this is a numpy array of size
969 $1 \times \text{dimension}$. The default is a $1 \times \text{dimension}$ array of zeros.

970

971 For `algorithm = 'Stretch'`, this is a list of n_s points, each defined as
972 numpy arrays with size $1 \times \text{dimension}$, where n_s is the size of the en-
973 semble being propagated. [9]. The default value in the table above is
974 not valid for `algorithm = 'Stretch'`.

975 • **verbose:**

976 Specifies whether text is written to the terminal declaring the status of
977 the MCMC evaluation.

978 `verbose` is of boolean type with default `verbose = False`.

979 *Output Attributes:*

980 • **samples:**

981 The generated samples are returned as a numpy array of dimension
982 $\text{nsamples} \times \text{dimension}$.

983 • **accept_ratio:**

984 Acceptance ratio of the chain, an acceptance ratio between 10 and 50%
985 could be targeted, see **Diagnostics**, Section 6.2.1.

986 **Examples:**

987 Two examples illustrating the use of the **MCMC** class are provided in the follow-
988 ing Jupyter notebooks.

989 • **MCMC_Example1.ipynb:**

990 In this example, the three MCMC algorithms are used to generate 1000
991 samples from a two-dimensional Rosenbrock pdf. The Rosenbrock pdf is
992 defined as a function directly in the script, using both the `pdf_target`
993 and `log_pdf_target` input parameters of the **MCMC** class.

994 • **MCMC_Example2.ipynb:**

995 In this example, the three MCMC algorithms are used to generate 1000
996 samples from a two-dimensional Rosenbrock pdf. The Rosenbrock pdf is
997 passed into the **MCMC** class as a string.

998 5.2.4 UQpy.SampleMethods.IS

999 **Theory**

1000 Importance sampling (IS) is based on the idea of concentrating the
1001 distribution of the sampling points in regions of the input space. This allows
1002 to compute expectations $E_{\mathbf{x} \sim p}[f(\mathbf{x})]$ where $f(\mathbf{x})$ is small outside of a small
1003 region of the input space; thus the need to focus sampling around that
1004 small region. To this end, a sample \mathbf{x} is drawn from a proposal distribution
1005 $q(\mathbf{x})$ and re-weighted to correct for the discrepancy between the sampling
1006 distribution q and the true distribution p . The weight of the sample \mathbf{x} is
1007 estimated as $\mathbf{w}(\mathbf{x}) = p(\mathbf{x})/q(\mathbf{x})$, where the quantity $p(\cdot)/q(\cdot)$ is called the
1008 likelihood ratio. In the case where p is only known up to a constant, i.e.,
1009 one can only evaluate $\tilde{p}(\mathbf{x})$, where $p(\mathbf{x}) = \frac{\tilde{p}(\mathbf{x})}{Z}$, IS can be used by further
1010 normalizing the weights (self-normalized IS). Figure 8 shows the weighted
1011 samples obtained when using IS to estimate a 2d Gaussian target distribution
 p , sampling from a uniform proposal distribution q .

Figure 8: IS: samples are generated from a uniform distribution, then weighted to provide an approximation of the target Gaussian distribution.

1012

1013

1014 **Using the IS Class**

1015 The IS class is imported using the following command:

```
1016 from UQpy.SampleMethods import IS
```

1017 The attributes of the IS class are listed below:

1018

IS Class Attribute Definitions					
Attribute	Input/Output	Type	Options	Default	Required
<code>nsamples</code>	Input	<i>integer</i>		None	*
<code>pdf_proposal</code>	Input	See <code>Distribution</code> Class			*
<code>pdf_proposal_params</code>	Input	See <code>Distribution</code> Class			
<code>log_pdf_target</code> [†]	Input	<i>string, strings list</i> <i>function, functions list</i>		None	*
<code>pdf_target</code> [†]	Input	<i>string, strings list</i> <i>function, functions list</i>		None	*
<code>pdf_target_params</code>	Input	<i>list</i> <i>list/ndarray list</i>		None

<code>pdf_target_copula_params</code>	Input	See <code>Distribution</code> Class			
<code>samples</code>	Output	<i>ndarray</i>			
<code>weights</code>	Output	<i>ndarray</i>			
<code>unnormalized_log_weights</code>	Output	<i>ndarray</i>			

Detailed Description of IS Class Attributes:

Input Attributes:

- **pdf_proposal:**

A string or list of strings providing the names of the proposal distribution (or its independent marginals) from which to sample. The distribution is then built using the `Distribution` class (see Section 6.1) as `p=Distribution(dist_name=pdf_proposal)`. This distribution must have an `rvs` method, as well as a `log_pdf` (or `pdf`) method.

- **pdf_proposal_params:**

Parameters of the proposal pdf, used when calling the `rvs` and `log_pdf` methods of the proposal distribution.

See `Distributions` module, Section 6.1.

- **log_pdf_target:** This input defines the log of the target pdf $\log(\tilde{p}(x))$, it can either be:

- A string or list of strings providing the names of the proposal distribution (or its independent marginals), then `Distribution` will be called. This `Distribution` instance must have a `log_pdf` method.
- A function that evaluates the target log pdf, given a matrix of samples x . This function must take in as input parameters at least one input x , namely the samples where to evaluate the log pdf; the function must be able to evaluate the log pdf of several samples at once, i.e., for an input x of size (nsamples, dimension), the function must return nsamples values of the log pdf. Additionally, it can

[†]One of `pdf_target` or `log_pdf_target` is required.

1044 take as inputs the parameters of the density functions `params` and
1045 copula parameters `copula_params`.

1046 Alternatively, the target pdf can be defined using `pdf_target`, the reader
1047 is referred to Figure 7 from the MCMC class for more detailed explanations
1048 on how the code checks for the definition of the target distribution.

1049 • `pdf_target`: Alternative to defining `log_pdf_target`. This input can
1050 either be:

- 1051 – A string or list of strings providing the names of the proposal dis-
1052 tribution (or its independent marginals), then `Distribution` will
1053 be called. This `Distribution` instance must have a `log_pdf` or a
1054 `pdf` method.
- 1055 – A function that evaluates the target pdf, given a matrix of samples
1056 x . Same comments apply as for `log_pdf_target` in this case.

1057 • `pdf_target_params`:
1058 Parameters of the target pdf to be passed as arguments the target dis-
1059 tribution.

1060 • `pdf_target_copula`:
1061 Name of the copula of the target pdf, if it exists, used only if the input
1062 `pdf_target` is defined as a list of strings.
1063 See `Distributions` module, Section 6.1.

1064 • `pdf_target_copula_params`:
1065 Parameters of the copula of the target pdf, if it exists, to be passed as
1066 arguments the target distribution.
1067 See `Distributions` module, Section 6.1.

1068 • `nsamples`
1069 Specifies the number of samples to be generated. `nsamples` must be
1070 specified, there is no default value.

1071 *Output Attributes:*

- 1072 • `samples`:
1073 The samples of the `IS` class are returned as a numpy array of dimension
1074 `nsamples × dimension`.

1075 • **weights:**
1076 The weights of the **IS** class are returned as a numpy array of dimension
1077 **nsamples**.

1078 • **unnormalized_weights:**
1079 The logarithm of the unnormalized weights of the **IS** class are returned
1080 as a numpy array of dimension **nsamples**.

1081 **Examples:**
1082 One example illustrating the use of the **IS** class are provided in the following
1083 Jupyter notebook.

1084 • **IS_Example1.ipynb:**
1085 In this example, **IS** is used to generate 500000 samples from a two-
1086 dimensional Rosenbrock pdf from a Uniform proposal distribution. The
1087 Rosenbrock pdf is defined as a function directly in the script.

1088 5.2.5 UQpy.SampleMethods.STS

1089 Theory

1090 Stratified Sampling [13, 18] is a variance reduction sampling technique. It
 1091 aims to distribute random samples on the complete sample space. The
 1092 sample space is divided into a set of space-filling and disjoint regions, called
 1093 strata and samples are generated inside each strata.

1094

1095 Using the STS Class

1096 STS is a class for stratified sampling. The STS class is imported using the
 1097 following command:

```
1098 from UQpy.SampleMethods import STS
```

1099 The attributes of the STS class are listed below:

1100

STS Class Attributes					
Attribute	Input/Output	Type	Options	Default	Required
dimension	Input	<i>integer</i>		<code>len(sts_design)</code>	
dist_name	Input	<i>string</i> <i>string list</i>	See Distributions	None	★
dist_params	Input	<i>ndarray list</i>		None	★
sts_design	Input	<i>int list</i>		None	
sts_criterion	Input	<i>string</i>	'random', 'centered'	'random'	
input_file	Input	<i>string</i>		None	
samples	Output	<i>ndarray</i>			
samplesU01	Output	<i>ndarray</i>			
strata	Output	<i>class object</i>	See Strata Class		

1101

1102 Detailed Description of STS Class Attributes:

1103

1104 *Input Attributes:*

- 1105 • **dimension:**

1106 A scalar integer value defining the dimension of the random variables.
 1107 It is not required if **sts_design** is defined.

- 1108 • **dist_name:**

1109 Defines the distributions for each random variable.

1110 **dist_name** may be a string or a list of strings.

1111 The string **dist_name[i]** is matched with with one of the available func-
 1112 tions in the **Distributions** module (see Sec. 6.1, Table 3) or the custom
 1113 distribution (again see Sec. 6.1).

1114 **dist_name** must be specified. There is no default value.

1115 • **dist_params:**
1116 Specifies the parameters for each distribution in **dist_name**.
1117 Each set of parameters is defined as a numpy array. **dist_params** is a
1118 list of arrays, with each item in the list corresponding to the associated
1119 random variable.
1120 Refer to the **Distributions** module in Section 6.1.
1121 **dist_params** must be specified. There is no default value.

1122 • **sts_design:**
1123 Specifies the number of strata in each dimension.
1124 **sts_design** specifies a stratification that breaks every dimension equally
1125 into a specified number of strata of the same size. For more complex
1126 strata geometries, the strata boundaries can be explicitly defined through
1127 a text input file. See **input_file** and the corresponding documentation
1128 in Section 5.2.6.
1129 **STS** places one sample in each stratum so the total number of samples
1130 drawn by **STS** is the product of the components of **sts_design**.
1131 Either **sts_design** or **input_file** is required.
1132 Example: **sts_design** = [2, 4, 3] specifies a three-dimensional strat-
1133 ified design with two strata in the first dimension, four strata in the
1134 second dimension, and three strata in the third dimension for a total of
1135 $2 \times 4 \times 3 = 24$ samples.

1136 • **sts_criterion:**
1137 A string specifying the technique used to generate a sample inside each
1138 strata.
1139 – ‘random’: Samples are drawn randomly in the strata.
1140 – ‘centered’: Samples are centered in the strata.
1141 Default is ‘random’.

1142 • **input_file:**
1143 Specifies the file path for a text file defining a stratification. See Section
1144 5.2.6.
1145 Either **sts_design** or **input_file** is required.

1146 *Output Attributes:*

```

1147     • samples:
1148       The generated samples. The samples are returned as a numpy array.

1149     • samplesU01:
1150       The untransformed samples drawn from the unit hypercube with dimension
1151       dimension.

1152     • strata:
1153       A class object that defines the strata on the unit hypercube with dimension
1154       dimension.

1155 Examples:
1156 Two examples illustrating the use of the STS class are provided in the following
1157 Jupyter notebooks.

1158     • STS_Example1.ipynb:
1159       In this example, 25 samples are drawn from an exponential distribution
1160       using stratified sampling with the strata specified using the sts_design
1161       input for a regular, equal probability stratification.

1162     • STS_Example2.ipynb:
1163       In this example, 6 samples are drawn from an exponential distribution
1164       using stratified sampling with the strata specified using an input_file
1165       ('strata.txt') to create an irregular stratification with unequal probability
1166       strata.

```

1167 5.2.6 UQpy.SampleMethods.Strata

1168 The **Strata** class is a supporting class for stratified sampling and its variants.
 1169 The class defines a rectilinear stratification of the unit hypercube. Strata
 1170 are defined by specifying a stratum origin as the coordinates of the stratum
 1171 corner nearest to the global origin and a stratum width for each dimension.

1172

1173 The attributes of the **STS** class are listed below:

1174

Strata Class Attributes					
Attribute	Input/Output	Type	Options	Default	Required
nstrata	Input	<i>int list</i>		None	
input_file	Input	<i>string</i>		None	
origins	Output	<i>ndarray</i>			
widths	Output	<i>ndarray</i>			
weights	Output	<i>ndarray</i>			

1175

1176 Detailed Description of Strata Class Attributes:

1177

1178 *Input Attributes:*

- 1179 • **nstrata:**

1180 Specifies the number of strata in each dimension. This is equivalent to
 1181 **sts_design** from the **STS** class. For additional details, see **STS** documen-
 1182 tation in Section 5.2.5.

1183 When calling the **Strata** class, the user must provide either **nstrata** or
 1184 a text file defining the strata specified through **input_file**.

- 1185 • **input_file:**

1186 Specifies the file path of for a text file defining a stratification.

1187 When calling the **Strata** class, the user must provide either **nstrata** or
 1188 a text file defining the strata specified through **input_file**.

1189 *File format:* This file must be a space delimited text file having
 1190 $2 \times \text{dimension}$ columns and the number of rows equal to the number
 1191 of strata. The first **dimension** columns correspond to the coordinates
 1192 in each dimension of the stratum origin. Columns **dimension+1** to
 1193 $2 \times \text{dimension}$ correspond to the stratum widths in each dimension.

1194 For example, to specify stratification with two 2-dimensional strata, the
 1195 text file might contain the following:

1196

1197 0.0 0.0 0.5 1.0

1198 0.5 0.0 0.5 1.0

1199

1200 The first stratum (row 1) has origin (0.0, 0.0) and has width 0.5 in
1201 dimension 1 and width 1.0 in dimension 2. The second stratum (row 2)
1202 has origin (0.5, 0.0) and has width 0.5 in dimension 1 and width 1.0
1203 in dimension 2.

1204 When manually assigning the strata definitions, the user must be careful
1205 to ensure that the stratification fills the space without overlap. That is,
1206 each strata that the user defines must be disjoint and the total volume
1207 of the strata must be equal to one (i.e. it must fill the unit hypercube).

1208 An example `input_file` can be found in ‘STS_Example2’ in the provided
1209 example Jupyter notebooks for the `STS` class.

1210 *Output Attributes:*

1211 • **origins:**

1212 Specifies the coordinates of the origin of each stratum.

1213 • **widths:**

1214 Specifies the width in each dimension of each stratum.

1215 • **weights:**

1216 The volume of each stratum (`=prod(widths)` for each stratum), **weights**
1217 are the probabilities assigned to each sample in a stratified sample design.

1218 5.2.7 UQpy.SampleMethods.RSS

1219 Theory

1220 This is a sample extension method, which uses a random or gradient-based
 1221 adaptive approach to reduce the variance of output statistical estimates.
 1222 This class divides the sample domain using either rectangular stratification
 1223 or voronoi cells. Fig(9) shows the work-flow of RSS class for different inputs
 attributes.

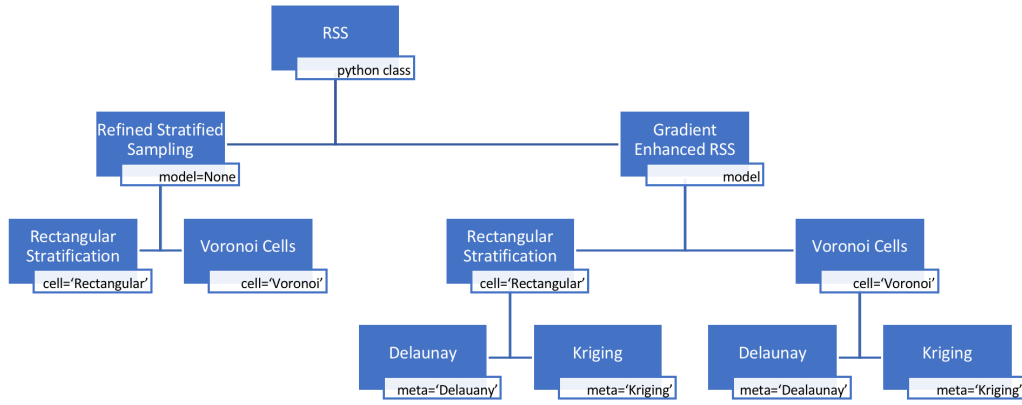

Figure 9: Work flow of RSS class.

1224

- 1225 • Refined Stratified Sampling (RSS)
 1226 Randomly selects the stratum to refine from the strata/cells with maxi-
 1227 mum weight, see [19] for a detailed explanation.
- Gradient-Enhanced Refined Stratified Sampling (GE-RSS)
 Selects the strata/cells with maximum stratum variance, which is esti-
 mated using Eq.(1), see [17] for a detailed explanation.

$$\hat{\sigma}_j^2 \approx \nabla f(x_j^*)^T \cdot \Sigma \cdot \nabla f(x_j^*) \cdot V_j \quad \forall j \quad (1)$$

1228 In case of rectangular stratification, selected strata is divided along the
 1229 maximum width to define new strata. In case of Voronoi cells, the new
 1230 sample is drawn from a sub-simplex, which is used for refinement.

1231

Using the RSS Class

The RSS class is imported using the following command:

```
from UQpy.SampleMethods import RSS
```

The attributes of the RSS class are listed below:

RSS Class Attributes					
Attribute	Input/Output	Type	Options	Default	Required
x	Input	RSS/STS <i>object</i>		None	★
model	Input	<i>string</i>	See <code>RunModel</code> Class		
meta	Input	<i>string</i>	'Delaunay' 'Kriging'	'Delaunay'	
cell	Input	<i>string</i>	'Rectangular' 'Voronoi'	'Rectangular'	
nsamples	Input	<i>int</i>		None	★
min_train_size	Input	<i>int</i>		nsamples	
step_size	Input	<i>float</i>		0.005	
corr_model corr_model_params reg_model n_opt	Input	See <code>Surrogates.Krig</code> Class			
samples	Output	<i>ndarray</i>			
values	Output	<i>ndarray</i>			

Detailed Description of RSS Class Attributes:

Input Attributes:

- **x**:

A class object generated using STS or RSS class. It contains the information about coordinates, stratification and weights corresponding to existing samples. This class requires an initial STS design to function.

- **model**

A string specifying the model script, which is used to evaluate the model at sample points. It is called with `RunModel` by setting `model_script = model` (see Section 5.1.3 for a detailed explanation). It is required for GE-RSS. If `model` is `None`, Refined Stratified Sampling is executed for sample extension.

- **meta**

A string specifying the surrogate model used to estimate the gradient of the model. 'Delaunay' creates a linear interpolator over the domain, whereas, 'Kriging' generates a Gaussian Process surrogate model using

1255 the `Krig` class (see Section 5.5.2). It is only required for the GE-RSS
 1256 method. The default is ‘Delaunay’.

- 1257 • **cell**
 1258 A string specifying how the sample space is stratified. This class supports
 1259 two types of stratification: ‘Rectangular’ and ‘Voronoi’. Default string
 1260 is ‘Rectangular’.
- 1261 • **nsamples**
 1262 An integer specifying the final size of extended samples.
- 1263 • **min_train_size**
 1264 An integer specifying the minimum number of samples used to generate a
 1265 local surrogate model to update the gradient of the model. Only required
 1266 if `meta = ‘Kriging’`.
- 1267 • **step_size**
 1268 A real number defining the step size to calculate the gradient using cen-
 1269 tral difference method.
- 1270 • **corr_model**
 1271 A string specifying the correlation model used to create the surrogate
 1272 model. Only required if `meta = ‘Kriging’`.
 1273 See section 5.5.2 for details.
- 1274 • **corr_model_params**
 1275 An array specifying initial values of the hyperparameters/scale paramet-
 1276 ers. Only required if `meta = ‘Kriging’`.
 1277 See section 5.5.2 for details.
- 1278 • **reg_model**
 1279 A string specifying the regression model used to create the surrogate
 1280 model. Only required if `meta = ‘Kriging’`.
 1281 See section 5.5.2 for details.
- 1282 • **n_opt**
 1283 Number of times the hyperparameter optimization problem is to be
 1284 solved with different starting points. Only required if `meta = ‘Kriging’`.
 1285 See section 5.5.2 for details.
 1286 Here, this is done for only for the first sample set. After that, the
 1287 hyperparameters from the previous Kriging model is used as a starting
 1288 point.

1289 *Output Attributes:*

- 1290 • **samples:**
1291 The samples of the `RSS` class are returned as a numpy array of dimension
1292 `nsamples × dimension`. `dimension` is the same as `x.samples`.
- 1293 • **values:**
1294 Function value at the sample points evaluated using `RunModel`, returned
1295 as a numpy array.

1296 **Examples:**

1297 Examples illustrating the use of the `RSS` class are provided in the following
1298 Jupyter notebooks.

- 1299 • `RSS_Example1.ipynb`:
1300 This example demonstrates the use of `RSS` with rectangular stratification.
1301 First, `STS` is used to generate 16 samples from a uniform probability
1302 distribution. `RSS` class is then used to extend the sample size to 18
1303 points. Plots illustrate the modified stratification with the new samples.
1304 Further, samples from the `RSS` class are used again to extend the sample
1305 size to 100.
- 1306 • `RSS_Example2.ipynb`:
1307 This example demonstrates the use of `RSS` with Voronoi stratification.
1308 First, `STS` is used to generate 16 samples from a uniform probability
1309 distribution. `RSS` class is then used to extend the sample size to 18
1310 points. Plots illustrate the modified stratification with the new samples.
1311 Further, samples from the `RSS` class are used again to extend the sample
1312 size to 100.
- 1313 • `RSS_Example3.ipynb`:
1314 This example illustrate the use of Gradient Enhanced Refined Stratified
1315 Sampling with rectangular stratification. ‘Delaunay’ is used to estimate
1316 the gradient. `RSS` class extends the 16 samples from `STS` class to 200
1317 samples for a strongly nonlinear function.
- 1318 • `RSS_Example4.ipynb`:
1319 This example illustrate the use of Gradient Enhanced Refined Stratified
1320 Sampling with rectangular stratification. ‘Kriging’ is used to estimate
1321 the gradient. `RSS` class extends the 16 samples from `STS` class to 200
1322 samples for a strongly nonlinear function.

- 1323 • `RSS_Example5.ipynb`:
1324 This example illustrate the use of Gradient Enhanced Refined Stratified
1325 Sampling with Voronoi stratification. ‘Deluanay’ is used to estimate the
1326 gradient. `RSS` class extends the 16 samples from `STS` class to 200 samples
1327 for a strongly nonlinear function.
- 1328 • `RSS_Example6.ipynb`:
1329 This example illustrate the use of Gradient Enhanced Refined Stratified
1330 Sampling with Voronoi stratification. ‘Kriging’ is used to estimate the
1331 gradient. `RSS` class extends the 16 samples from `STS` class to 200 samples
1332 for a strongly nonlinear function.

1333 5.2.8 UQpy.SampleMethods.Simplex

Theory

Edeling et al. [6] propose a method to generate uniformly distributed sample inside a simplex, whose coordinates are expressed by ζ_k and n_d is the dimension. First, generate n_d independent uniform random variables on $[0, 1]$, i.e. r_q , then compute

$$\mathbf{M}_{\mathbf{n}_d} = \zeta_0 + \sum_{i=1}^{n_d} \left[\prod_{j=1}^i r_{n_d-j+1}^{\frac{1}{n_d-j+1}} \right] (\zeta_i - \zeta_{i-1})$$

1334 The M_{n_d} is n_d dimensional array defining the coordinates of new sample.

Figure 10: Random point inside a 2-D Simplex.

1335 Using the Simplex Class

1336 The Simplex class is imported using the following command:

1337 `from UQpy.SampleMethods import Simplex`

1338 The attributes of the Simplex class are listed below:

1339

Simplex Class Attributes					
Attribute	Input/Output	Type	Options	Default	Required
nodes	Input	<i>ndarray/list</i>		None	★
nsamples	Input	<i>integer</i>		1	★
samples	Output	<i>ndarray</i>			

1341 Detailed Description of Simplex Class Attributes:

1342

1343 *Input Attributes:*

1344 • **nodes:**
1345 An array or list defining the coordinates of the vertices of simplex. This
1346 is a required attribute. There is no default value.

1347 • **nsamples**
1348 Specifies the number of samples to be generated in the simplex.
1349 **nsamples** must be specified. Default value is 1.

1350 *Output Attributes:*

1351 • **samples:**
1352 The samples of the **Simplex** class are returned as a numpy array of
1353 dimension **nsamples** \times **dimension**. Dimension is equal to number of
1354 vertices - 1.

1355 **Examples:**
1356 One example illustrating the use of the **Simplex** class is provided in the fol-
1357 lowing Jupyter notebook.

1358 • **Simplex_Example1.ipynb:**
1359 In this example, **Simplex** is used to generate 10 samples inside a two-
1360 dimensional simplex from a uniform distribution.

1361 5.3 Inference Module

1362 The goal in inference can be twofold: 1) given a model, parameterized by
1363 parameter vector θ , and some data \mathcal{D} , learn the value of the parameter vector
1364 that best explains the data; 2) given a set of candidate models $\{m_i\}_{i=1:M}$ and
1365 some data \mathcal{D} , learn which model best explains the data. UQpy supports the
1366 following inference algorithms for parameter estimation:

- 1367 • `MLEstimation` (parameter estimation by maximum likelihood, frequen-
1368 tist approach),
- 1369 • `BayesParamEstimation` (parameter estimation using MCMC or IS,
1370 Bayesian approach).

1371 and the following algorithms for model selection:

- 1372 • `InfoModelSelection` (model selection using information theoretic cri-
1373 teria),
- 1374 • `BayesModelSelection` (Bayesian model class selection).

1375 The capabilities of UQpy and associated classes are summarized in Fig. 11.

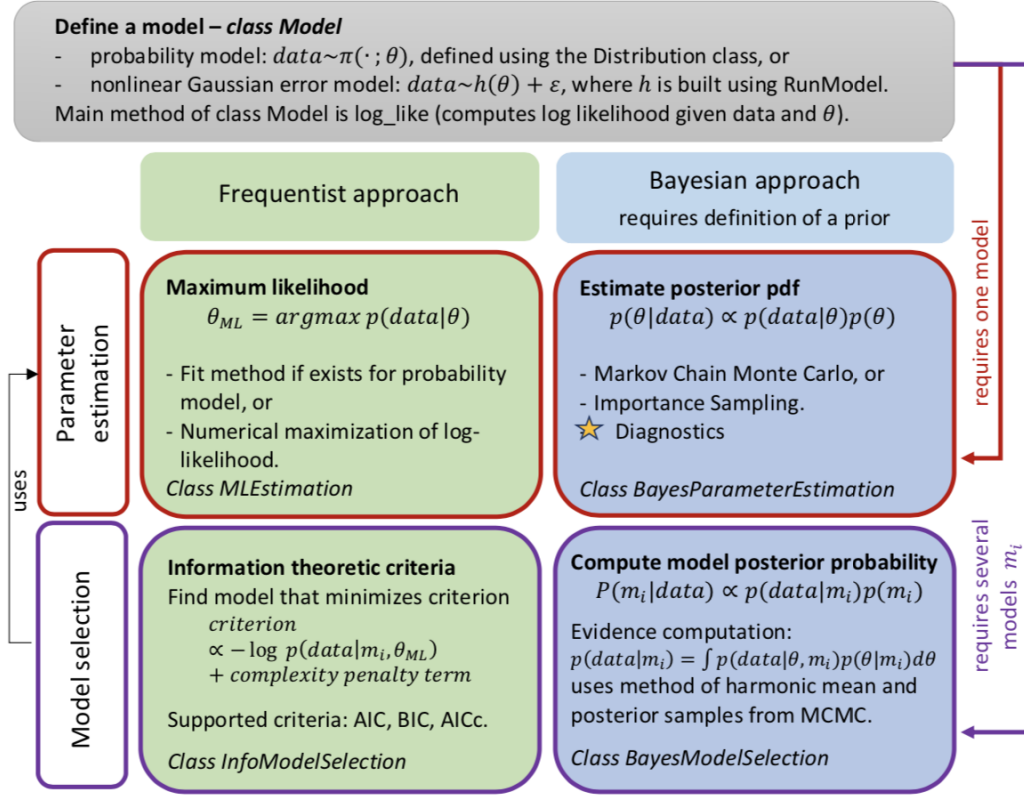

Figure 11: UQpy Inference module.

1376 5.3.1 UQpy.Inference.Model

1377 In all cases, the user must first create, for each model studied, an instance of
 1378 the class *Model*, which can be either:

- 1379 • A probability model π , where $\mathcal{D} \sim \pi(\cdot|\theta)$; π is a distribution defined
 1380 using the *Distributions* module (Section 6.1);
- 1381 • A user-defined model $h(\theta)$ given in a python script (see requirements
 1382 in the *RunModel* Section 5.1). The associated probabilistic model for
 1383 inference is defined as $\mathcal{D} = h(\theta) + \epsilon$, where the error ϵ is assumed to be
 1384 Gaussian with zero mean.

1385 The class defines a `log_like` method as a function that evaluates, given a data
 1386 vector \mathcal{D} and a parameter vector θ , the log likelihood of the data $\ln p(\mathcal{D}|\theta)$. For
 1387 a probability model, \mathcal{D} must be of size (n, d) where d is the output dimension
 1388 of the distribution (e.g., d=2 if π defines a 2-dimensional Gaussian pdf), and

1389 n is the number of i.i.d. samples from that distribution. For a python model,
 1390 \mathcal{D} must be a one-dimensional vector.

1391 The following table lists the attributes of the class `Model`.

1392

Model Class Attributes					
Attribute	Input/Output	Type	Options	Default	Required
<code>model_type</code>	Input	<i>str</i>	'pdf' 'python'	None	★
<code>n_params</code>	Input	<i>int</i>		None	★
<code>model_name</code>	Input	<i>str</i>	See <code>Distribution</code> Class		
<code>model_script</code>	Input	<i>str</i>		None	
<code>model_object_name</code> <code>input_template</code> <code>var_names</code> <code>output_script</code> <code>output_object_name</code> <code>ntasks</code> <code>cores_per_task</code> <code>nodes</code> <code>model_dir</code> <code>cluster</code> <code>resume</code>	Input	see <code>UQpy.RunModel</code>			
<code>error_covariance</code>	Input	<i>float/ndarray</i>		1	
<code>prior_name</code> <code>prior_params</code> <code>prior_copula</code> <code>prior_copula_params</code>	Input	Used to define a <code>Distribution</code> object for the prior			
<code>fixed_params</code>	Input	<i>list</i>		None	
<code>log_like</code>	Output	<i>function</i>			
<code>prior</code>	Output	<code>Distribution</code> object			

1393

1394 *Common Input Attributes:*

- 1395 • **model_type:**
 1396 Specifies the class of model to be inferred. **Inference** can perform in-
 1397 ference for two different types of models:
- 1398 – `model_type` = 'pdf': Inference on a probability model defined
 1399 through the `Distributions` module.
 - 1400 – `model_type` = 'python': Inference on a generic python numerical
 1401 or analytical model that is callable using `RunModel`.
- 1402 • **n_params:**
 1403 `n_params` is the number of parameters in the model to be inferred, it is
 1404 a required input of the class.
- 1405 • **prior_name, prior_params, prior_copula, prior_copula_params:**
 1406 In a Bayesian analysis, a prior for the parameters θ should be defined,

1407 which is done by calling `Distribution(dist_name=prior_name,`
1408 `copula=prior_copula)`. This `Distribution` must have a `log_pdf` or a
1409 `pdf` method, which are evaluated using input parameters `prior_params,`
1410 `prior_copula_params`.

1411 • **fixed_params:**

1412 The model can also take in as input a vector of fixed parameters, which
1413 are not being learned. In this context, the model is fully parameterized
1414 by the vector $\begin{Bmatrix} \theta \\ \text{fixed_params} \end{Bmatrix}$, where θ is being learned during inference
1415 (the fixed parameters are appended at the end of the full parameter
1416 vector given as an input to the function that computes the data).

1417 *Input Attributes, model_type = 'pdf':*

1418 • **model_name:**

1419 A probability model is defined by calling `Distribution(dist_name=`
1420 `model_name)`. `model_name` can thus be a string that defines a distribu-
1421 tion supported within `UQpy`, or a user-defined distribution. This distribu-
1422 tion must have either a `log_pdf` method (preferred), or a `pdf` method.
1423 Very importantly, these methods should be functions that accept ex-
1424 actly two inputs: `x` the point where to compute the pdf/log pdf, and
1425 `params` the value of the parameter vector characterizing that distribu-
1426 tion. This means for instance that if one wants to define a distribution
1427 with a copula and copula parameters, they must define a custom dis-
1428 tribution that is parameterized by a single parameter vector that con-
1429 catenates the parameters of the marginals and the parameters of the
1430 copula into a single vector `params` (an example is provided in the file
1431 `'bivariate_normal_gumbel.py'`).

1432 *Input Attributes, model_type = 'python':*

1433 • **model_script:**

1434 For a model defined using `RunModel`, `model_script` points to the `'py'`
1435 file that computes \mathcal{D} , given as input a parameter vector θ (input `samples`
1436 of the function defined in `model_script`).

1437 • **error_covariance:**

1438 The error term is assumed to have zero-mean and a known fixed covari-
1439 ance, given by `error_covariance`. `error_covariance` can be a scalar
1440 (in which case the covariance matrix is the identity times that value) or
1441 a full covariance; default is 1.

1442 • Inputs to RunModel:
1443 Class `Model` also accepts various input attributes which relate
1444 to the definition of the model in the `RunModel` module, namely,
1445 `model_object_name`, `input_template`, `var_names`, `output_script`,
1446 `output_object_name`, `ntasks`, `cores_per_task`, `nodes`, `resume`,
1447 `verbose`, `model_dir`, `cluster`.

1448 • `model_name`:
1449 This input is not required for a python model, but useful when perform-
1450 ing model selection for instance. If this input is `None`, the model name is
1451 built by concatenating the input `model_script` and `model_object_name`.

1452 *Output Attributes:*

1453 • `log_like`:
1454 A function that computes the log-likelihood of the data given the pa-
1455 rameters.

1456 • `prior`:
1457 The prior distribution of the parameter vector, which will be used in
1458 Bayesian inference.

1459 **Examples:**

1460 Examples illustrating how to define a model can be found in various
1461 jupyter notebooks, referenced in the following sections. In particular, the
1462 `Maximum Likelihood Example.ipynb` Jupyter notebook shows the definition
1463 of three different models:

- 1464 • a probability model with a distribution supported by `UQpy`,
- 1465 • a probability model defined in a user-defined script,
- 1466 • a python model defined with `RunModel` (a regression model).

1467 Also, a more advanced example can be found in the Parameter estimation
1468 - `material homogenization.ipynb` Jupyter notebook. The model consists in
1469 running a couple of finite element analyses, using the external python package
1470 `Sfepy`. This example illustrates how one can wrap `UQpy` around existing codes
1471 to perform inference.

1472 5.3.2 UQpy.Inference.MLEstimation

Theory

Computes the maximum likelihood estimator $\hat{\theta}$ of the model parameters, i.e.

$$\hat{\theta} = \operatorname{argmax}_{\Theta} p(\mathcal{D}|\theta)$$

1473 For a probabilistic model of the form $\mathcal{D} = h(\theta) + \epsilon$, $\epsilon \sim N(0, \sigma)$ with σ
 1474 fixed and known and independent measurements \mathcal{D}_i , maximizing the likeli-
 1475 hood is mathematically equivalent to minimizing the sum of squared residuals
 1476 $\sum_i (\mathcal{D}_i - h(\theta))^2$.

1477 When the model is a probability model that possesses a `fit` method
 1478 (see Distribution module), this fit method is used to compute the maximum
 1479 likelihood parameters. Otherwise, i.e., for python models or distribution
 1480 models without existing fit methods (custom distribution or distributions
 1481 with copula for instance), a numerical optimization procedure is performed
 1482 using the `scipy.optimize.minimize` module.

1483

1484 Using the MLEstimation Class

1485 The following table summarizes the attributes of the MLEstimation class.

1486

MLEstimation Class Attributes					
Attribute	Input/Output	Type	Options	Default	Required
<code>model</code>	Input	Model object		None	★
<code>data</code>	Input	<i>ndarray</i>		None	★
<code>method_optim</code>	Input	<i>string</i>	See input method of <code>scipy.optimize.minimize</code>		
<code>x0</code>	Input	<i>ndarray</i>	See <code>scipy.optimize.minimize</code>		
<code>bounds</code>	Input	<i>list</i>	See <code>scipy.optimize.minimize</code>		
<code>iter_optim</code>	Input	<i>int</i>		1	
<code>verbose</code>	Input	<i>boolean</i>		False	
<code>param</code>	Output	<i>ndarray</i>			
<code>max_log_like</code>	Input	<i>float</i>			

1488 Detailed descriptions of attributes are provided in the following.

1489

1490 *Input Attributes:*

- 1491 • **model:**
 1492 Model for which to performed inference, should be an instance of class
 1493 `Model`.
- 1494 • **data:**
 1495 Data \mathcal{D} used to perform inference. see Section 5.3.1 for details on the
 1496 size of the data matrix.

- 1497 • **method_optim, x0, bounds:**
 1498 These inputs are only used when a maximization of the log likelihood is
 1499 performed using `scipy.optimize.minimize` (not a fit method), to de-
 1500 termine some properties of the maximization procedure. They refer to
 1501 inputs **method**, **x0** and **bounds** of the `scipy.optimize.minimize` mod-
 1502 ule, respectively.
- 1503 • **iter_optim:**
 1504 Defines the number of times the optimization procedure is run, with ran-
 1505 dom initial guesses (it ignores **x0** in this case). The random initial guesses
 1506 are sampled from the bounds provided by the user (input **bounds**), or
 1507 between $[0, 1]$ if no bounds are provided. The identified maximum likeli-
 1508 hood parameter vector is the one that yields the maximum log likelihood
 1509 over all **iter_optim** runs of the maximization procedure.
- 1510 • **verbose:**
 1511 Specifies whether text is written to the terminal declaring the status of
 1512 the **MLEstimation** evaluation.
 1513 **verbose** is of boolean type with default **verbose = False**.

1514 *Output Attributes:*

- 1515 • **param:**
 1516 The maximum likelihood estimate of the parameter vector $\hat{\theta}$.
- 1517 • **max_log_like:**
 1518 The value of the log likelihood evaluate at $\hat{\theta}$, $\ln p(\mathcal{D}|\hat{\theta})$.

1519 **Examples:**

1520 An example illustrating the use of the **MLEstimation** class is provided in the
 1521 **Maximum Likelihood Example.ipynb** Jupyter notebook. Three different mod-
 1522 els are studied:

- 1523 • a probability model with an existing fit method,
- 1524 • a probability model without a fit method (custom distribution or dis-
 1525 tribution with copulas), which thus requires numerical optimization for
 1526 maximum likelihood estimation,
- 1527 • a python model defined with **RunModel** (a regression model).

1528 5.3.3 UQpy.Inference.BayesParameterEstimation

Theory

Given some data \mathcal{D} , a parameterized model for the data, and a prior probability density for the model parameters $p(\theta)$, `BayesParameterEstimation` draws samples from the Bayesian posterior pdf of the model parameters using Markov Chain Monte Carlo or Importance Sampling. Via Bayes theorem, the posterior pdf is as follows:

$$p(\theta|\mathcal{D}) = \frac{p(\mathcal{D}|\theta)p(\theta)}{p(\mathcal{D})}$$

1529 Note that if no prior is defined in the model, the prior pdf is chosen as unin-
1530 formative, i.e., $p(\theta) = 1$ (cautionary note, this is an improper prior). UQpy
1531 also provides a diagnostics function, see `Utilities` module, which performs
1532 some diagnostics on the outputs of the MCMC and IS procedures.

1533 The code in `BayesParameterEstimation` simply defines a log-posterior
1534 function that evaluates $\tilde{p} = p(\mathcal{D}|\theta)p(\theta) \propto p(\theta|\mathcal{D})$. This function is then pro-
1535 vided as the `log_pdf_target` input of the MCMC or IS classes.

1536 Outputs of the class `BayesParameterEstimation` are samples from the
1537 posterior pdf (weighted samples in the case of IS, such that if one requires a
1538 set of un-weighted samples to represent the posterior pdf, one can use the
1539 `resample` function provided in the `Utilities` module).

1540

1541 Using the BayesParameterEstimation class

1542 The following table summarizes the attributes of the `BayesParameterEstimation`
1543 class.

1544

BayesParameterEstimation Class Attributes					
Attribute	Input/Output	Type	Options	Default	Required
model	Input	Model object		None	★
data	Input	ndarray		None	★
sampling_method	Input	string	‘MCMC’ ‘IS’	‘MCMC’	
nsamples	Input	int		None	★
pdf_proposal pdf_proposal_params	Input	See IS class			
pdf_proposal_type pdf_proposal_scale algorithm jump nburn seed	Input	See MCMC class			
verbose	Input	boolean		False	
samples	Output	ndarray			
weights	Output	ndarray			
accept_ratio	Output	float			

Detailed descriptions of the attributes are provided in the following.

Input Attributes:

- **model:**
Model for which to perform inference. It should be an instance of class `Model`. See Section 5.3.1
- **data:**
Data \mathcal{D} used to perform inference. See Section 5.3.1 for details on the size of the data matrix.
- **sampling_method:**
Specifies how to draw samples from the posterior. `BayesParameterEstimation` supports two options:
 - ‘MCMC’: [default] Samples from the posterior via Markov Chain Monte Carlo
 - ‘IS’: Samples from the posterior via Importance Sampling
- **nsamples:**
Number of generated samples (weighted if IS) from the posterior.
- **pdf_proposal, pdf_proposal_params:**
Used only if `sampling_method` = ‘IS’.

1565 These inputs define the proposal distribution to sample from in Impor-
1566 tance Sampling (see `IS` class in the `SamplingMethods` module, section
1567 5.2.4). If no proposal distribution is provided, the algorithm samples
1568 from the prior defined for `model`.

1569 Either a proposal distribution or a prior in `model` must be provided.

- 1570 • `pdf_proposal_type`, `pdf_proposal_scale`, `nburn`, `jump`, `algorithm`,
1571 `seed`:

1572 Used only if `sampling_method` = ‘MCMC’.

1573 These inputs define the inputs to MCMC (see `MCMC` class in the
1574 `SamplingMethods` module, Section 5.2.3).

1575 If no `seed` is given, maximum likelihood estimation is first performed
1576 and the maximum likelihood estimate of the parameter vector is used as
1577 the seed for MCMC.

- 1578 • `verbose`:

1579 Specifies whether text is written to the terminal declaring the status of
1580 the `BayesParameterEstimation`.

1581 *Output Attributes:*

- 1582 • `samples`:

1583 An array containing the samples drawn from the posterior density.
1584 `samples` has dimension `nsamples` × `dim(θ)`.

- 1585 • `weights`:

1586 An array containing the importance weights for the samples.

1587 Used only if `sampling_method` = ‘IS’.

- 1588 • `accept_ratio`:

1589 The acceptance ratio of the Markov Chain.

1590 Used only if `sampling_method` = ‘MCMC’.

1591 **Examples:**

1592 Examples illustrating the use of the `BayesParameterEstimation` class are
1593 provided in the following Jupyter notebooks:

- 1594 • `Bayesian_parameter_estimation_MCMC.ipynb`

- 1595 • `Bayesian_parameter_estimation_IS.ipynb`

1596 These scripts illustrate Bayesian parameter estimation using MCMC and IS,
1597 respectively, for two different models:

- 1598 • A probability model (Gaussian pdf, learn the posterior pdfs of its mean
1599 and variance from data),
- 1600 • A python model defined with `RunModel` (regression model of the form
1601 $h(\theta) = \theta_1 x + \theta_2 x^2$, learn the posterior pdf of θ from data).

1602 The notebooks also illustrate how to use `Diagnostics` to check both the MCMC
1603 and IS outputs.

1604 **Advanced Example – Using Inference for material parameter esti-**
1605 **mation:**

1606 A more complex example illustrating the use of the `Inference` module for pa-
1607 rameter estimation is provided in the Parameter estimation - material homog-
1608 enization.ipynb Jupyter notebook. This example learns the material param-
1609 eters, Young modulus and Poisson ratio, of the two materials in a composite
1610 microstructure (matrix and fibers), when data is assumed to be measured at
1611 the macro level from tensile tests on a specimen. In this example, the model
1612 consists in running two FE codes, one simulating the behavior of the macro
1613 specimen, the other the behavior of a representative element of the microstruc-
1614 ture. The FE simulations require the package `Sfepy`. The example is inspired
1615 from one of the `Sfepy` examples ([5]). The notebook illustrates the use of the
1616 `Model`, `MLEstimation` and `BayesParameterEstimation` modules of `UQpy`.

1617 5.3.4 UQpy.InfoModelSelection

1618 Theory

1619 Model selection refers to the task of selecting a statistical model from a set of
1620 candidate models, given some data. A good model is one that is capable of
1621 explaining the data well. Given models of the same explanatory power, the
1622 simplest model should be chosen (Occam's razor). Several simple information
1623 theoretic criteria can be used to compute a model's quality and perform model
1624 selection ([4]). UQpy implements three criteria:

- Bayesian information criterion (BIC)

$$BIC = \ln(n)k - 2 \ln(\hat{L})$$

- Akaike information criterion (AIC)

$$AIC = 2k - 2 \ln(\hat{L})$$

- Corrected formula for AIC (AICc), for small data sets

$$AICc = AIC + \frac{2k(k+1)}{n-k-1}$$

1625 For all formula above, k is the number of parameters characterizing the model,
1626 \hat{L} is the maximum value of the likelihood function, and n is the number of
1627 data points. The best model is the one that minimizes the criterion. All three
1628 formulas have a model fit term (find the model that minimizes the negative
1629 log likelihood) and a penalty term that increases as the number of model
1630 parameters (model complexity) increases. A probability can be defined for
1631 each model as $P(m_i) \propto \exp\left(-\frac{\text{criterion}}{2}\right)$.

1632 **InfoModelSelection** calls **MLEstimation** to perform maximum likelihood
1633 estimation for each model. Thus inputs to **MLEstimation** can also be
1634 provided to **InfoModelSelection**, as lists of length equal to the number
1635 of models. The procedure yields several outputs as attributes of the
1636 class, such as the fitted maximum likelihood parameters for all models,
1637 corresponding log likelihood values, model probabilities and so on (see details
1638 below). These outputs are given as lists, either sorted in the order they
1639 were given in the input **candidate_models** (if input **sorted_outputs** is
1640 set to *False*), or sorted in descending value of the model probabilities (default).

1641 Using the InfoModelSelection class

1642 The following table summarizes the attributes of the **InfoModelSelection**
1643 class.
1644

1645

InfoModelSelection Class Attributes					
Attribute	Input/Output	Type	Options	Default	Required
candidate_models	Input	<i>list</i> of <code>Model</code> objects		None	★
data	Input	<i>ndarray</i>		None	★
method	Input	<i>string</i>	'AIC' 'BIC' 'AICc'	'AIC'	
sorted_outputs	Input	<i>boolean</i>		True	
x0	Input	<i>list</i> of length <code>len(candidate_models)</code>	Inputs to <code>MLEstimation</code> class for each model		
iter_optim					
bounds					
method_optim					
models	Output	<i>list</i> of <code>Model</code> objects			
model_names	Output	<i>list</i> of <i>strings</i>			
fitted_params	Output	<i>list</i> of <i>ndarrays</i>			
criteria	Output	<i>list</i> of <i>floats</i>			
penalty_terms	Output	<i>list</i> of <i>floats</i>			
probabilities	Output	<i>list</i> of <i>floats</i>			

1646

1647

Detailed descriptions of the attributes are provided in the following.

1648

1649

Input Attributes:

1650

- **candidate_models:**

1651

The list of candidate models. Each of them must be an instance of class `Model`. See Section 5.3.1.

1652

1653

- **data:**

1654

Data \mathcal{D} used to perform inference. See section 5.3.1 for details on the size of the data matrix.

1655

1656

- **method:**

1657

Criterion used for model selection. `InfoModelSelection` supports three criteria:

1658

1659

- ‘AIC’: [default] Akaike Information Criterion

1660

- ‘BIC’: Bayesian Information Criterion

1661

- ‘AICc’: Akaike Information Criterion with small sample correction

1662

- **sorted_outputs:**

1663

If set to `True` [default], the outputs are returned as lists ordered by decreasing values of the model probabilities.

1664

1665

If set to `False`, the outputs are returned as lists ordered in the same way as in `candidate_models`.

1666

1667 • `x0`, `iter_optim`, `bounds`, `method_optim`:
 1668 Inputs to the `MLEstimation` class. See Section 5.3.2.
 1669 These inputs should be given as lists of length equal to the number of
 1670 models, ordered in the same way as `candidate_models`.

1671 *Output Attributes:*

1672 All outputs are lists of length equal to the number of models, either ordered
 1673 in the same way as the input list `candidate_models`, or in order of decreasing
 1674 model probabilities.

1675 • `models`:
 1676 Instances of `Model` class. These are the same as `candidate_models` but
 1677 possibly ordered differently.

1678 • `model_name`:
 1679 Names of the models, Inherited from the `Model` objects.

1680 • `fitted_params`:
 1681 Maximum likelihood estimate of the parameter vector, for all models.

1682 • `criteria`:
 1683 Value of the criterion chosen for model selection, see respective equation
 1684 in the Theory section above.

1685 • `penalty_terms`:
 1686 Each criterion can be written as $criterion = -2\ln(\hat{L}) + \text{penalty_term}$,
 1687 where the first term $-2\ln(\hat{L})$ is a data-fit term, while the penalty term
 1688 penalizes against complex models. Observing the penalty terms allows
 1689 the user to understand if a model is chosen because it fits the data better
 1690 than other models, or if it fits the data in the same way than competing
 1691 models but is somehow less complex and thus preferred according to
 1692 Occam's razor.

1693 • `probabilities`:
 1694 Models probabilities based on data, computed as $P(m_i) \propto$
 1695 $\exp\left(-\frac{criterion}{2}\right)$ for each model m_i

1696 **Examples:**

1697 An example illustrating the use of the `InfoModelSelection` class is provided
 1698 in the `Model.selection.info.criteria.ipynb` Jupyter notebook. Two different ex-
 1699 amples are studied:

1700 • Selection between three univariate probability models,

- 1701 • Selection between three python models (polynomial regression models of
1702 different orders).

1703 5.3.5 UQpy.Inference.BayesModelSelection

In the Bayesian approach to model selection, the posterior probability of each model is computed as:

$$P(m_i|\mathcal{D}) = \frac{p(\mathcal{D}|m_i)P(m_i)}{\sum_j p(\mathcal{D}|m_j)P(m_j)}$$

where the evidence (also called marginal likelihood) $p(\mathcal{D}|m_i)$ involves an integration over the parameter space:

$$p(\mathcal{D}|m_i) = \int_{\Theta} p(\mathcal{D}|m_i, \theta)p(\theta|m_i)d\theta$$

Currently, calculation of the evidence is performed using the method of the harmonic mean ([2]):

$$p(\mathcal{D}|m_i) = \left[\frac{1}{B} \sum_{b=1}^B \frac{1}{p(\mathcal{D}|m_i, \theta_b)} \right]^{-1}$$

1704 where $\theta_1, \dots, \theta_B$ are samples from the posterior pdf of θ . In UQpy, these samples
 1705 are obtained by running `BayesParameterEstimation` using MCMC. However,
 1706 note that this method is known to yield evidence estimates with large variance.
 1707 Future releases of UQpy will include more robust methods for computation of
 1708 model evidences. Also, it is known that results of such Bayesian model selec-
 1709 tion procedure usually highly depends on the choice of prior for the parameters
 1710 of the competing models, thus the user should carefully define such priors when
 1711 creating instances of the `Model` class.

1712 Similarly to the `InfoModelSelection` class, the `BayesModelSelection`
 1713 class takes as inputs the data, candidate models, along with additional in-
 1714 puts that are lists of length the number of models and define inputs to the
 1715 MCMC procedure for all models. Additionally, `BayesModelSelection` takes
 1716 as input the prior probabilities of the models. The procedure yields outputs
 1717 such as posterior model probabilities, evidence etc. as lists, either sorted in
 1718 the same order as given in `candidate_models` or sorted by decreasing model
 1719 probabilities.

1720

BayesModelSelection Class Inputs		
Attribute/Method	Type	Comment
<code>candidate_models</code>	<i>list of models</i>	required
<code>data</code>	<i>ndarray</i>	required
<code>prior_probabilities</code>	<i>ndarray</i>	default $\frac{1}{M}$ for all M models
<code>sorted_outputs</code>	<i>boolean</i>	default <i>True</i>
1721 <code>n_samples</code>	<i>lists of length the number of candidate models</i>	inputs of class <code>BayesParameterEstimation</code> (uses MCMC)
<code>pdf_proposal_type</code>		
<code>pdf_proposal_scale</code>		
<code>algorithm</code>		
<code>jump</code>		
<code>nburn</code>		
<code>seed</code>		

1722 The following points provide some explanations about these input param-
1723 eters:

- 1724 • **candidate_models:**
1725 The list of candidate models, each of them must be an instance of class
1726 `Model`.
- 1727 • **data:**
1728 Data \mathcal{D} used to perform inference, see section 5.3.1 for details on the size
1729 of the data matrix.
- 1730 • **prior_probabilities:**
1731 Prior model probabilities $P(m_i)$ as a *list of floats* or *ndarray*, default is
1732 a list of $\frac{1}{M}$ for all M models.
- 1733 • **sorted_outputs:**
1734 If set to *True* (default), the outputs are returned as lists ordered by
1735 decreasing values of the model probabilities. If set to *False*, the outputs
1736 are returned as lists ordered in the same way as in `candidate_models`.
- 1737 • **pdf_proposal_type, pdf_proposal_scale, algorithm, jump, nburn,**
1738 **seed:**
1739 Inputs to the `BayesParameterEstimation` class, see corresponding
1740 section. These inputs should be given as lists or length the number of
1741 models, ordered in the say way as `candidate_models`.

1742 The following table provides a summary of the outputs attributes of the
1743 class `BayesModelSelection`.

BayesModelSelection Class Output Attributes	
Attribute	Type
<code>models</code>	<i>list of models</i>
<code>model_names</code>	<i>list of strings</i>
<code>evidences</code>	<i>list of floats</i>
<code>mcmc_outputs</code>	<i>list of instances of <code>BayesParameterEstimation</code></i>
<code>probabilities</code>	<i>list of floats</i>

The following points provide details about the outputs attributes of the class `BayesModelSelection`. All these outputs are lists of length the number of models, either ordered in the same way as the input list `candidate_models`, or in order of decreasing model probabilities.

- **models:**

Instances of class `models`, same as `candidate_models` but possibly ordered in a different way.

- **model_names:**

Names of the models.

- **evidences:**

Value of the evidence $p(\mathcal{D}|m_i)$ for each model m_i .

- **mcmc_outputs:** Objects of the class `BayesParameterEstimation`, which have as attributes both the samples of the posterior pdf for all models and the acceptance ratio of the chains. See section on `BayesParameterEstimation`.

- **probabilities:**

Value of the posterior probability $P(m_i|\mathcal{D})$ for each model m_i .

Examples:

An example illustrating the use of the `BayesModelSelection` class is provided in the Bayesian model selection.ipynb Jupyter script. The example studied is the selection between three python models (polynomial regression models of different orders). Gaussian priors are assumed for the parameters, rendering the problem tractable, meaning that the true posterior pdfs and values of the evidence for each model can be computed analytically. Analytical results are compared with outputs of the `BayesModelSelection` algorithm.

1770 5.4 Reliability Module

1771 Reliability of a system refers to the assessment of its probability failure (i.e.
 1772 the structure no longer satisfies some performance measures), given the model
 1773 uncertainty in the structural, environmental and load parameters. Given a
 1774 vector of random variables $\mathbf{X} = \{X_1, X_2, \dots, X_n\} \in \mathcal{D}_{\mathbf{X}} \subset \mathbb{R}^n$, where \mathcal{D} is the
 1775 domain of interest and $f_{\mathbf{X}}(\mathbf{x})$ is its joint probability density function then, the
 1776 probability that the system will fail is defined as

$$P_f = \mathbb{P}(g(\mathbf{X}) \leq 0) = \int_{D_f} f_{\mathbf{X}}(\mathbf{x}) d\mathbf{x} = \int_{\{\mathbf{x}: g(\mathbf{x}) \leq 0\}} f_{\mathbf{X}}(\mathbf{x}) d\mathbf{x} \quad (2)$$

1777 where $g(\mathbf{X})$ is the so-called performance function. Formulation of reliability
 1778 methods in `UQpy` is made on the standard normal space $\mathbf{U} \sim \mathcal{N}(\mathbf{0}, \mathbf{I}_n)$
 1779 which means that a nonlinear isoprobabilistic transformation from the
 1780 generally non-normal parameter space $\mathbf{X} \sim f_{\mathbf{X}}(\cdot)$ is required (see Section
 1781 5.7). The performance function in the standard normal space is denoted $G(\mathbf{U})$.

1782

1783 The `Reliability` module consists of classes and functions to provide
 1784 simulation-based estimates of probability of failure from a given user-defined
 1785 computational model and failure criterion. It is imported in a python script
 1786 using the following command:

1787 `from UQpy import Reliability`

1788 The `Reliability` module has the following classes, each corresponding to a
 1789 method for probability of failure estimation:

Class	Method
SubsetSimulation	Subset Simulation
TaylorSeries	FORM/SORM

1791 Each class can be imported individually into a python script. For example,
 1792 the `SubsetSimulation` and the `TaylorSeries` classes can be imported to a
 1793 script using the following commands:

1794 `from UQpy.SampleMethods import SubsetSimulation`

1795 `from UQpy.SampleMethods import TaylorSeries`

1796 The following subsections describe each class, their respective inputs and at-
 1797 tributes, and their use.

1798 5.4.1 UQpy.Reliability.TaylorSeries

1799 **Theory**

1800 These reliability methods utilize a Taylor series expansion to approximate
 1801 the performance function $g(\mathbf{X})$ locally at a design point to approximate the
 1802 integral in Eq.(2). In this category belong the First Order Reliability Method
 1803 (FORM) and the Second Order Reliability Method (SORM). In FORM, the
 1804 performance function is linearized according to

$$G(\mathbf{U}) \approx G(\mathbf{U}^*) + \nabla G|_{\mathbf{U}^*} (\mathbf{U} - \mathbf{U}^*)^\top \quad (3)$$

1805 where \mathbf{U}^* is expansion point, $G(\mathbf{U})$ is the performance function evaluated in
 1806 the standard normal space and $\nabla G|_{\mathbf{U}^*}$ is the gradient of $G(\mathbf{U})$ evaluated at
 1807 \mathbf{U}^* . The probability failure can be calculated by

$$P_{f,\text{form}} = \Phi(-\beta_{HL}) \quad (4)$$

1808 where $\Phi(\cdot)$ is the standard normal cumulative distribution function and $\beta_{HL} =$
 1809 $\|\mathbf{U}^*\|$ is the norm of the design point known as the Hasofer-Lind reliability in-
 1810 dex [11] calculated with the Hasofer-Lind-Rackwitz-Fiessler (HLRF) algorithm
 1811 [15]. In SORM the performance function is approximated by a second-order
 1812 Taylor series around the design point according to

$$G(\mathbf{U}) = G(\mathbf{U}^*) + \nabla G|_{\mathbf{U}^*} (\mathbf{U} - \mathbf{U}^*)^\top + \frac{1}{2} (\mathbf{U} - \mathbf{U}^*)^\top \mathbf{H} (\mathbf{U} - \mathbf{U}^*) \quad (5)$$

1813 where \mathbf{H} is the Hessian matrix of the second derivatives of $G(\mathbf{U})$ evaluated
 1814 at \mathbf{U}^* . After the design point \mathbf{U}^* is identified and the probability of failure
 1815 $P_{f,\text{form}}$ is calculated with FORM a correction is made according to

$$P_{f,\text{sorm}} = \Phi(-\beta_{HL}) \prod_{i=1}^{n-1} (1 + \beta_{HL} \kappa_i)^{-\frac{1}{2}} \quad (6)$$

1816 where κ_i is the i -th curvature.

1817

1818 **Using the TaylorSeries class**

1819 The `TaylorSeries` class is imported using the following command:

```
1820 from UQpy.Reliability import TaylorSeries
```

1821 The attributes of the `TaylorSeries` class are listed below:

1822

TaylorSeries Class Attributes					
Attribute	Input/Output	Type	Options	Default	Required
dimension	Input	<i>integer</i>		None	★
dist_name	see UQpy.Distribution				★
dist_params	see UQpy.Distribution				★
corr	see UQpy.Transformation			np.eye(dimension)	
method	Input	<i>string</i>	'FORM' 'SORM'	None	★
n_iter	Input	<i>integer</i>	n_iter > 0	n_iter = 1000	
algorithm	Input	<i>string</i>	'HL'	None	
seed	Input	<i>ndarray</i>		np.zeros((1, dimension))	
model_script model_object_name input_template var_names output_script ntasks cores_per_task resume output_object_name	Input	see UQpy.RunModel			
DesignPoint_X	Output	<i>ndarray</i>			
DesignPoint_U	Output	<i>ndarray</i>			
Prob_FORM	Output	<i>float</i>			
Prob_SORM	Output	<i>float</i>			
HL.beta	Output	<i>float</i>			
iterations	Output	<i>integer</i>			

1823

1824 Detailed Description of TaylorSeries Class Attributes:

1825

1826 *Input Attributes:*

1827

1828 • **dimension:**
A scalar integer value defining the dimension of the random variables.

1829

1830 • **dist_name**
Specifies the probability distribution model for each random variable.
1831 Details about this attribute can be found in UQpy.Distribution.

1832

1833 • **dist_params**
Specifies the parameters for each probability model. Details about this
1834 attribute can be found in UQpy.Distribution.

1835

1836 • **corr**
Specifies the correlation structure of the random vector. If not defined,
1837 we assume independent random variables.

$$\text{corr} = \begin{bmatrix} 1.0 & 0.0 & \dots & 0.0 \\ 0.0 & 1.0 & \dots & 0.0 \\ \vdots & \vdots & \ddots & \vdots \\ 0.0 & 0.0 & \dots & 1.0 \end{bmatrix}$$

Details about this attribute can be found in `UQpy.Transformation`.

- **method:**

Specifies the method from the family of Taylor Series expansion. `TaylorSeries` supports two commonly-used algorithms.

- ‘FORM’:
First Order Reliability Method.
- ‘SORM’:
Second Order Reliability Method.

- **n_iter:**

Maximum number of iterations of the HLRF method.

- **algorithm:**

Specifies the algorithm used to solve the optimization problem for finding the design point. `TaylorSeries` currently supports the **Hasofer-Lind** method, specified by ‘HL’.

- **seed:**

Specifies the initial point in the original parameter space (not in the standard normal space) for the search algorithm in the Hasofer-Lind method.

- **RunModel attributes:**

`TaylorSeries` operates with a performance function specified through a computational model. This computational model is called using `RunModel`. `TaylorSeries` therefore requires all attributes of `RunModel` to be input.

Output Attributes:

- **DesignPoint_X:**

Design point in the original parameter space.

- 1865 • **DesignPoint_U**
1866 Design point in the standard normal space.
1867
- 1868 • **Prob_FORM**
1869 Probability of failure obtained with FORM.
- 1870 • **Prob_SORM**
1871 Probability of failure calculated with SORM (if `method='SORM'`).
- 1872 • **HL_beta**
1873 Hasofer-Lind reliability index.
- 1874 • **iterations**
1875 Total number of function calls.

1876 **TaylorSeries Examples:**

1877 An examples illustrating the use of the **TaylorSeries** class is provided in the
1878 following Jupyter notebook.

- 1879 • **TaylorSeries_Example1.ipynb:**
1880 This example involves two simple structural reliability problems defined
1881 in a two-dimensional parameter spaces. The first problem consists of
1882 a resistance R and a stress S . The failure happens when the stress is
1883 higher than the resistance, leading to the following limit-state function:

$$g(\mathbf{X}) = R - S \leq 0 \quad (7)$$

1884 where $\mathbf{X} = \{R, S\}$. The two random variables are independent and dis-
1885 tributed according to the following normal distributions: $R \sim N(200, 20)$
1886 and $S \sim N(150, 10)$.

1887 In the second problem the the limit-state function is defined as:

$$g(\mathbf{X}) = \frac{1}{\sqrt{d}} \sum_{i=1}^d x_i + \beta \leq 0 \quad (8)$$

1888 where $\mathbf{X} = \{X_1, X_2\}$ are two independent standard normal random vari-
1889 ables $X_1 \sim N(0, 1)$ and $X_2 \sim N(0, 1)$.

1890 5.4.2 UQpy.Reliability.SubsetSimulation

1891 Theory

1892 In the subset simulation method [3], the probability of failure P_f is approxi-
 1893 mated by a product of probabilities of more frequent events. That is, the failure
 1894 event $G = \{\mathbf{u} \in \mathbb{R}^n : G(\mathbf{u}) \leq 0\}$, is expressed as the of union of M nested
 1895 intermediate events G_1, G_2, \dots, G_M such that $G_1 \supset G_2 \supset \dots \supset G_M$, and
 1896 $G = \cap_{i=1}^M G_i$. The intermediate failure events are defined as $G_i = \{G(\mathbf{u}) \leq b_i\}$,
 1897 where $b_1 > b_2 > \dots > b_M = 0$ are positive thresholds selected such that each
 1898 conditional probability $P(G_i|G_{i-1})$, $i = 2, 3, \dots, M - 1$ equals a target prob-
 1899 ability value p_0 . The probability of failure P_f is estimated as:

$$P_f = P(\cap_{i=1}^M G_i) = P(G_1) \prod_{i=2}^M P(G_i|G_{i-1}) \quad (9)$$

1900 where the probability $P(G_1)$ is computed through Monte Carlo simulations.
 1901 In order to estimate the conditional probabilities $P(G_i|G_{i-1})$, $j = 2, 3, \dots, M$
 1902 generation of Markov Chain Monte Carlo (MCMC) samples from the condi-
 1903 tional pdf $p_{\mathbf{U}}(\mathbf{u}|G_{i-1})$ is required. In the context of subset simulation, the
 1904 Markov chains are constructed through a two-step acceptance/rejection cri-
 1905 terion. Starting from a Markov chain state \mathbf{x} and a proposal distribution
 1906 $q(\cdot|\mathbf{x})$, a candidate sample \mathbf{y} is generated. In the first stage, the sample \mathbf{y} is
 1907 accepted/rejected with probability

$$\alpha = \min \left\{ 1, \frac{p(\mathbf{y})q(\mathbf{x}|\mathbf{y})}{p(\mathbf{x})q(\mathbf{y}|\mathbf{x})} \right\} \quad (10)$$

1908 and in the second stage is accepted/rejected based on whether the sample
 1909 belongs to the failure region G_j . Currently `SubSetSimulation` supports the
 1910 the Component-wise Modified Metropolis Hastings (MMH) and the affine
 1911 invariant ensemble MCMC algorithm (see Section 5.2).

1912

1913 Using the TaylorSeries class

1914 The `SubsetSimulation` class is imported using the following command:

```
1915 from UQpy.Reliability import SubsetSimulation
```

1916 The attributes of the `SubsetSimulation` class are listed below:

SubsetSimulation Class Attributes					
Attribute	Input/Output	Type	Options	Default	Required
dimension	Input	<i>integer</i>		1	
samples_init	Input	<i>nparray</i>		None	
nsamples_ss	Input	<i>integer</i>		None	★
p_cond	Input	<i>float</i>	$0 < p_cond < 1$	$p_cond = 0.1$	
algorithm pdf_target.type pdf_target log_pdf_target pdf_target.params pdf_target.copula pdf_target.copula.params jump seed nburn pdf_proposal.type pdf_proposal.scale	Input	see <code>UQpy.SampleMethods.MCMC</code>			★
model_script model_object_name input_template var_names output_script output_object_name ntasks cores_per_task nodes model_dir cluster resume	Input	see <code>UQpy.RunModel</code>			★
samples	Output	<i>nparray list</i>			
g	Output	<i>nparray list</i>			
g_level	Output	<i>list</i>			
pf	Output	<i>float</i>			

Detailed Description of SubsetSimulation Class Attributes:

Input Attributes:

- **dimension:**

A scalar integer value defining the dimension of the random variables.

- **samples_init**

Specifies the initial samples for subset/level 0. The size of the array **samples_init** must be **nsamples_ss**×**dimension**. These samples can be generated in any way the user chooses.

If **samples_init** is not specified, the subset/level 0 samples are drawn internally in **SubsetSimulation** using the component-wise Modified Metropolis-Hastings algorithm. (**MCMC algorithm** = 'MMH')

- **nsamples_ss**

Specifies the number of samples to be generated in each conditional level

(i.e. per subset). `nsamples_ss` must be specified. There is no default value.

- **p_cond**

Specifies the conditional probability for each subset.

The current implementation does not allow for variable conditional probabilities (i.e. setting different conditional probabilities for each level).

The current implementation does not allow for the conditional probabilities to be defined implicitly by instead specifying the intermediate failure domains explicitly.
- **algorithm:**

Specifies the MCMC algorithm used to generate samples in each conditional level. `SubsetSimulation` currently supports two commonly-used algorithms.

 - ‘MMH’:

Component-wise modified Metropolis-Hastings algorithm. For a description of the algorithm, see [3].
 - ‘Stretch’:

Affine invariant ensemble sampler employing “stretch” moves. For a description of the algorithm, see [9].

`SubsetSimulation` currently does not support the conventional Metropolis-Hastings algorithm.
- **pdf_target_type:**

This is used for Markov Chain Monte Carlo (MCMC) sampling from the conditional probability densities in subset simulation. For details, the user is referred to documentation for `UQpy.SampleMethods.MCMC` in Section 5.2.3
- **pdf_target:**

This is used for Markov Chain Monte Carlo (MCMC) sampling from the conditional probability densities in subset simulation. For details, the user is referred to documentation for `UQpy.SampleMethods.MCMC` in Section 5.2.3
- **log_pdf_target:**

This is used for Markov Chain Monte Carlo (MCMC) sampling from the conditional probability densities in subset simulation. For details,

1966 the user is referred to documentation for `UQpy.SampleMethods.MCMC` in
1967 Section 5.2.3

1968 • **pdf_target_params:**
1969 This is used for Markov Chain Monte Carlo (MCMC) sampling from
1970 the conditional probability densities in subset simulation. For details,
1971 the user is referred to documentation for `UQpy.SampleMethods.MCMC` in
1972 Section 5.2.3

1973 • **pdf_target_copula:**
1974 This is used for Markov Chain Monte Carlo (MCMC) sampling from
1975 the conditional probability densities in subset simulation. For details,
1976 the user is referred to documentation for `UQpy.SampleMethods.MCMC` in
1977 Section 5.2.3

1978 • **pdf_target_copula_params:**
1979 This is used for Markov Chain Monte Carlo (MCMC) sampling from
1980 the conditional probability densities in subset simulation. For details,
1981 the user is referred to documentation for `UQpy.SampleMethods.MCMC` in
1982 Section 5.2.3

1983 • **jump:**
1984 This is used for Markov Chain Monte Carlo (MCMC) sampling from
1985 the conditional probability densities in subset simulation. For details,
1986 the user is referred to documentation for `UQpy.SampleMethods.MCMC` in
1987 Section 5.2.3

1988 • **seed:**
1989 This is used for Markov Chain Monte Carlo (MCMC) sampling from
1990 the conditional probability densities in subset simulation. For details,
1991 the user is referred to documentation for `UQpy.SampleMethods.MCMC` in
1992 Section 5.2.3

1993 • **nburn:**
1994 This is used for Markov Chain Monte Carlo (MCMC) sampling from
1995 the conditional probability densities in subset simulation. For details,
1996 the user is referred to documentation for `UQpy.SampleMethods.MCMC` in
1997 Section 5.2.3

1998 • **pdf_proposal_type:**
1999 This is used for Markov Chain Monte Carlo (MCMC) sampling from
2000 the conditional probability densities in subset simulation. For details,

2001 the user is referred to documentation for `UQpy.SampleMethods.MCMC` in
2002 Section 5.2.3

2003 • `pdf_proposal_scale`:
2004 This is used for Markov Chain Monte Carlo (MCMC) sampling from
2005 the conditional probability densities in subset simulation. For details,
2006 the user is referred to documentation for `UQpy.SampleMethods.MCMC` in
2007 Section 5.2.3

2008 • `model_script`
2009 This is used to evaluate the model at each sample point using the
2010 `RunModel` class. For details, the user is referred to documentation for
2011 `UQpy.RunModel` in Section 5.1.

2012 Note that a computational model must be specified using `model_script`.
2013 Without this model, `SubsetSimulation` cannot run.

2014 • `model_object_name`
2015 This is used to evaluate the model at each sample point using the
2016 `RunModel` class. For details, the user is referred to documentation for
2017 `UQpy.RunModel` in Section 5.1.

2018 • `inpt_template`
2019 This is used to evaluate the model at each sample point using the
2020 `RunModel` class. For details, the user is referred to documentation for
2021 `UQpy.RunModel` in Section 5.1.

2022 • `var_names`
2023 This is used to evaluate the model at each sample point using the
2024 `RunModel` class. For details, the user is referred to documentation for
2025 `UQpy.RunModel` in Section 5.1.

2026 • `output_script`
2027 This is used to evaluate the model at each sample point using the
2028 `RunModel` class. For details, the user is referred to documentation for
2029 `UQpy.RunModel` in Section 5.1.

2030 • `output_object_name`
2031 This is used to evaluate the model at each sample point using the
2032 `RunModel` class. For details, the user is referred to documentation for
2033 `UQpy.RunModel` in Section 5.1.

- 2034 • **ntasks**
2035 This is used to evaluate the model at each sample point using the
2036 RunModel class. For details, the user is referred to documentation for
2037 UQpy.RunModel in Section 5.1.
- 2038 • **cores_per_task**
2039 This is used to evaluate the model at each sample point using the
2040 RunModel class. For details, the user is referred to documentation for
2041 UQpy.RunModel in Section 5.1.
- 2042 • **nodes**
2043 This is used to evaluate the model at each sample point using the
2044 RunModel class. For details, the user is referred to documentation for
2045 UQpy.RunModel in Section 5.1.
- 2046 • **model_dir**
2047 This is used to evaluate the model at each sample point using the
2048 RunModel class. For details, the user is referred to documentation for
2049 UQpy.RunModel in Section 5.1.
- 2050 • **cluster**
2051 This is used to evaluate the model at each sample point using the
2052 RunModel class. For details, the user is referred to documentation for
2053 UQpy.RunModel in Section 5.1.
- 2054 • **resume**
2055 This is used to evaluate the model at each sample point using the
2056 RunModel class. For details, the user is referred to documentation for
2057 UQpy.RunModel in Section 5.1.

2058 *Output Attributes:*

- 2059 • **samples:**
2060 Contains the sample values from each conditional level as a list of numpy
2061 arrays.
2062 Each item of the list is a numpy array containing the sam-
2063 ples from the corresponding conditional level. For example,
2064 SubsetSimulation.samples[0] contains a numpy array of dimension
2065 nsamples_ss×dimension with the samples from conditional level 0 (i.e.
2066 the initial sample set).

- 2067 • **g**
2068 Returns the scalar values of the performance function evaluated by the
2069 computational model at each point in **samples**. **g** is structured in the
2070 same manner as **samples** (a *numpy array list*) with each entry equal to
2071 the performance function evaluation of the corresponding sample.

2072 By convention, failure of a given sample **sample[i][j]** is defined by
2073 **g[i][j] < 0**, where **i** indexes the conditional level and **j** indexes the
2074 sample number. For use with **SubsetSimulation**, the user's compu-
2075 tational model must return a scalar value that follows this convention.
2076 The value is passed from **RunModel** into **SubsetSimulation** through the
2077 attribute **RunModel.model_eval.QOI** as detailed in Section 5.1.
- 2078 • **g_level**
2079 Specifies the value of the performance function for each conditional level.
2080 **g_level** is structured as a list with each entry of the list equal to the value
2081 of the corresponding performance function at the respective conditional
2082 level. For example, **g_level[3]** corresponds to the performance function
2083 value that defines the fourth subset.

2084 Note that **g_level** is implicitly defined by the samples and **p_cond**. **UQpy**
2085 currently does not support the direct assignment of conditional perfor-
2086 mance levels.
- 2087 • **pf**
2088 Probability of failure estimate from subset simulation

2089 **SubsetSimulation Examples:**

2090 An example illustrating the use of the **SubsetSimulation** class is provided in
2091 the following Jupyter notebook.

- **SubsetSimulation.Example1.ipynb:**
In this example, the probability of failure for a 2-dimensional problem
with standard normal random variables is estimated with performance
function given by:

$$g(\mathbf{u}) = -\frac{1}{\sqrt{2}} \sum_{i=1}^2 u_i + 3.0902$$

2092 5.5 Surrogates Module

2093 The **Surrogates** module consists of classes and functions to build simplified
 2094 mathematical expressions to interpolate data and serve as a meta-model, sur-
 2095rogate model, or emulator. It is imported in a python script using the following
 2096 command:

```
2097 from UQpy import Surrogates
```

2098 The **Surrogates** module has the following classes, each corresponding to a
 2099 different surrogate model form:

	Class	Method
2100	SROM	Stochastic Reduced Order Model
	Krig	Kriging

2101 5.5.1 UQpy.Surrogates.SROM

Theory

SROM takes a set of samples and attributes of a distribution and optimizes the sample probability weights according to the method of Stochastic Reduced Order Models as defined by Grigoriu [10]. SROM constructs a reduce order model for arbitrary random variables.

$$\tilde{X} = \begin{cases} x_1 & \text{probability } p_1^{(opt)} \\ \vdots & \\ x_m & \text{probability } p_m^{(opt)} \end{cases}$$

This class identify the probability/weights associated with sample, such that total error between distribution, moments and correlation of random variables is minimized. This optimization problem can be express as:

$$\begin{aligned} \min_{\mathbf{p}} \quad & \sum_{u=1}^3 \alpha_u e_u(\mathbf{p}) \\ \sum_{k=1}^m p_k = 1 \quad & \text{and} \quad p_k \geq 0, \quad k = 1, 2, \dots, m \end{aligned}$$

where $\alpha_1, \alpha_2, \alpha_3 \geq 0$ are constants defining the relative important of distribution, moments and correlation error between the reduce order model and actual random variables in the objective function.

$$e_1(p) = \sum_{i=1}^d \sum_{k=1}^m w_F(x_{k,i}; i) (\hat{F}_i(x_{k,i}) - F_i(x_{k,i}))^2$$

$$e_2(p) = \sum_{i=1}^d \sum_{r=1}^q w_\mu(r; i) (\hat{\mu}(r; i) - \mu(r; i))^2$$

$$e_3(p) = \sum_{i,j=1,\dots,d; j>i} w_r(i, j) (\hat{r}(i, j) - r(i, j))^2$$

2102 Here, F and \hat{F} denote the marginal distribution of \mathbf{X} and $\hat{\mathbf{X}}$ (reduced order
2103 model). Similarly, μ and $\hat{\mu}$ are marginal moments and r and \hat{r} are correlation
2104 matrix of \mathbf{X} and $\hat{\mathbf{X}}$. This class only consider first and second order moment
2105 about origin, i.e. $q=2$. And, ‘m’ is number of samples and ‘d’ is number of
2106 random variables.

2107 This method is explained in detail in Grigoriu [10].

2108

2109 Using the SROM Class

2110 The SROM class is imported using the following command:

2111 `from UQpy.Surrogates import SROM`

2112 The attributes of the SROM class are listed below:

SROM Class Attribute Definitions			
Attribute	Input/Output	Required	Optional
samples	Input	★	
cdf_target	Input	★	
cdf_target_params	Input	★	
properties	Input		★
2113 moments	Input	★	
correlation	Input		★
weights_error	Input		★
weights_distribution	Input		★
weights_moments	Input		★
weights_correlation	Input		★
sample_weights	Output		

2114 A brief description of each attribute can be found in the table below:

2115

SROM Class Attributes			
Attribute	Type	Options	Default
<code>samples</code>	<i>ndarray</i>		None
<code>cdf_target</code>	<i>function/string list</i>		None
<code>cdf_target_params</code>	<i>ndarray list</i>		None
<code>properties</code>	<i>boolean list</i>		[True, True, True, False]
2116 <code>moments</code>	<i>ndarray list</i>		None
<code>correlation</code>	<i>ndarray</i>		Identity matrix
<code>weights_error</code>	<i>list</i>		[1, 0.2, 0]
<code>weights_distribution</code>	<i>ndarray list</i>		Array of ones with size of <code>samples</code>
<code>weights_moments</code>	<i>ndarray list</i>		<code>moments</code> ⁻²
<code>weights_correlation</code>	<i>ndarray list</i>		
<code>sample_weights</code>	<i>ndarray</i>		

2117 **Detailed Description of SROM Class Attributes:**

2118

2119 *Input Attributes:*2120 • **samples:**

2121 An array or list containing the samples from which to build the Stochastic
2122 Reduced Order Model.

2123 • **cdf_target:**

2124 A list of functions or strings specifying the Cumulative Distribution
2125 Functions (CDFs) of the random variables.

2126

2127 If `cdf_target[i]` is a string, the distribution is matched with its
2128 corresponding cdf (`cdf`) in the `Distributions` module (see Sec. 6.1) or
2129 the cdf defined by ‘`custom_dist.py`’ (again see Sec. 6.1).

2130

2131 if `cdf_target[i]` is a function, it must be defined in the user’s Python
2132 script and passed directly as a function.

2133

2134 `cdf_target` can contain an arbitrary combination of strings and
2135 functions.

2136

2137 When `dimension > 1`, `cdf_target` may be specified as a string/function
2138 or a list of strings/functions assigned to each dimension. When specified
2139 as a string/function, the same cdf is specified for all dimensions.

2140 • **cdf_target_params:**

2141 A list of parameters corresponding to each random variable where the

parameters for each random variable are assigned as a numpy array.

Example: `cdf_target = ['Gamma']` and `cdf_target_params = [np.array([2,1,3])]` , where the random variables have gamma distribution with shape, shift and scale parameters equal to 2, 1 and 3 respectively.

- **properties:**
A boolean list specifying which properties of the distribution are to be included in the objective function. The list is of size 4 with the items of the list defined as follows:
 1. *distribution*: Minimize error in the match to the cumulative distribution function.
 2. *mean*: Minimize error in the first-order moments about the origin.
 3. *variance*: Minimize error in the second-order moments about the origin.
 4. *correlation*: Minimize error in correlation.

'True' includes the corresponding property in the objection function and 'False' excludes it.
- **moments:**
A list of numpy arrays specifying the first and second-order moments about the origin for each random variable. **SROM** supports the following size of **moments** array:
 - Array of size $1 \times \text{dimension}$: If error in either, but not both, first or second-order moments is included in **SROM**.
 - Array of size $2 \times \text{dimension}$: If error in both first and second-order moments are included in the **SROM**. The first row contains first-order moments and the second row contains the second-order moments.
- **correlation:**
An array specifying the correlations among the random variables. It is defined such that size of array is $\text{dimension} \times \text{dimension}$.
- **weights_error:**
SROM generates **sample_weights** which minimize the error between the

2175 cdf, moments, and correlation of the samples and the probability model.
2176 **weights_error** specifies weights assigned to each property in the ob-
2177 jective function as outlined in [10]. It is a list of size 3 with the items
2178 defined as follows:

- 2179 – *Item 1:* Weight assigned to the cumulative distribution function.
- 2180 – *Item 2:* Weight assigned to the first and second marginal moments.
- 2181 – *Item 3:* Weight assigned to the correlation matrix.

2182 Default values are set as in [10].

- 2183 • **weights_distribution:**
2184 A list of arrays containing weights defining the error in distribution at
2185 each sample of the random variables. **SROM** supports the following options
2186 for **weights_distribution**:
 - 2187 – **None:** Default value is defined as an array of the same size as
2188 **samples** with each value equal to 1. For default value, See [10].
 - 2189 – Array of size $1 \times \text{dimension}$: Equal weights are assigned to all
2190 samples in same dimension.
 - 2191 – Arbitrary array of the same size as **samples**: User specifies all
2192 weights explicitly.
- 2193 • **weights_moments:**
2194 A list of arrays containing weights defining the error in moments in each
2195 dimension. **SROM** supports the following options for **weights_moments**:
 - 2196 – **None:** Default value is defined as array of the same size as **moments**
2197 with each value equal to the reciprocal of the square of **moments**.
2198 For default value, see [10].
 - 2199 – Array of size $1 \times \text{dimension}$: Equal weights are assigned to both
2200 moments in same dimension.
 - 2201 – Array of size same as **moments**: User specifies all weights explicitly.
- 2202 • **weights_correlation:**
2203 A list of arrays containing the weights defining the error in correlation
2204 among random variables. It is define such that the size of the array is
2205 the same as **correlation**. For default value, See [10].

2206 *Output Attributes:*

2207 • **sample_weights:**
 2208 The generated SROM weights corresponding to **samples**. The samples
 2209 are returned as a numpy array with each sampling having a correspond-
 2210 ing weight.

2211 **Examples:**

2212 Two examples illustrating the use of the **SROM** class are provided in the follow-
 2213 ing Jupyter scripts.

- 2214 • **SROM.Example1.ipynb:**
 2215 In this example, the **STS** is used to generate 16 samples from a two-
 2216 dimensional Gamma pdf. The Gamma pdf is defined as a function di-
 2217 rectly in the script. Then, **SROM** is used to obtain sample weights.
- 2218 • **SROM.Example2.ipynb:**
 2219 In this example, sample weights are compared when **SROM** is called us-
 2220 ing default values for **weights_distribution** and **weights_moments** and
 2221 when **SROM** is called with user-defined values for **weights_distribution**
 2222 and **weights_moments**.
- 2223 • **SROM.Example3.ipynb:**
 2224 In this example, **SROM** is used to estimate the distribution of eigenvalues
 2225 of a spring-mass system, where stiffness of spring is treated as a random
 2226 variable, which follows gamma distribution. Distribution of eigenvalues
 2227 obtained by **SROM** method is compared with the Monte Carlo estimate.

2228 5.5.2 **UQpy.Surrogates.Krig**

Theory

Krig class defines an approximate surrogate model or response surface which can be used to predict function values at unknown location. Kriging gives the best unbiased linear predictor at the intermediate samples. **Krig** class generates a model \hat{y} that express the response surface as a realization of regression model and gaussian random process.

$$\hat{y}(x) = \mathcal{F}(\beta, x) + z(x)$$

Regression model (\mathcal{F}) is linear combination of ‘ p ’ chosen scalar basis function.

$$\mathcal{F}(\beta, x) = \beta_1 f_1(x) + \cdots + \beta_p f_p(x) = f(x)^T \beta$$

The random process $z(x)$ have mean zero and covariance is defined through correlation matrix($\mathcal{R}(\theta, s, x)$), which depends on hyperparameters(θ) and samples(s).

$$E[z(s)z(x)] = \sigma^2 \mathcal{R}(\theta, s, x)$$

Hyperparameters are estimate by maximizing the log-likelihood function.

$$\log(p(y|x, \theta)) = -\frac{1}{2}y^T \mathcal{R}^{-1}y - \frac{1}{2}\log(|\mathcal{R}|) - \frac{n}{2}\log(2\pi)$$

Once hyperparameters are computed, correlation matrix(\mathcal{R}) and basis functions are evaluated at sample points(F). Then, correlation coefficient(β) and process variance(σ^2) can be computed using following equations.

$$(F^T R^{-1} F)\beta^* = F^T R^{-1} Y$$

$$\sigma^2 = \frac{1}{m}(Y - F\beta^*)^T R^{-1}(Y - F\beta^*)$$

The final predictor function can be defined as:

$$\hat{y}(x) = f(x)^T \beta^* + r(x)^T R^{-1}(Y - F\beta^*)$$

2229

2230 Using the Krig Class

2231 The Krig class is imported using the following command:

2232 `from UQpy.Surrogates import Krig`

2233 The attributes of the Krig class are listed below:

Krig Class Attribute Definitions			
Attribute	Input/Output	Required	Optional
samples	Input	★	
values	Input	★	
reg_model	Input	★	
corr_model	Input	★	
corr_model_params	Input		★
bounds	Input		★
op	Input		★
n_opt	Input		★
interpolate	Output		
jacobian	Output		

2234

2235 A brief description of each attribute can be found in the table below:

2236

Krig Class Attributes			
Attribute	Type	Options	Default
<code>samples</code>	<i>ndarray/list</i>		None
<code>values</code>	<i>ndarray/list</i>		None
<code>reg_model</code>	<i>function/string</i>	Constant Linear Quadratic	None
<code>corr_model</code>	<i>function/string</i>	Exponential Gaussian Linear Cubic Spherical Spline	None
<code>corr_model_params</code>	<i>ndarray</i>		$[1, 1, \dots, 1]$
<code>bounds</code>	<i>list</i>		$[10^{-3}, 10^7]$
<code>op</code>	<i>boolean</i>		True
<code>n_opt</code>	<i>int</i>		1
<code>interpolate</code>	<i>function</i>		
<code>jacobian</code>	<i>function</i>		

2237

2238 Detailed Description of Krig Class Attributes:

2239

2240 *Input Attributes:*

2241

- **samples:**

2242

An array or list containing the samples from which to build the Kriging surrogate. Size of the array should be $m \times n$, where ‘ m ’ is number of samples and ‘ n ’ is dimension of sample space.

2243

2244

2245

- **values:**

2246

An array or list of function values evaluated at the samples. Size of the array should be $m \times q$, where ‘ q ’ is dimension of output space.

2247

2248

- **reg_model:**

2249

A function or string defining the trend of the model, which defines the basis function. There are three predefined regression model inside the class i.e. ‘Constant’, ‘Linear’ and ‘Quadratic’ regression model.

2250

2251

2252

Constant:

$$f_1(x) = 1 \quad J_f = [O_{n \times 1}]$$

Linear:

$$f_1(x) = 1, \quad f_2(x) = x_1, \quad \dots, \quad f_{n+1}(x) = x_n$$

$$J_f = [O_{n \times 1} \quad I_{n \times n}]$$

Quadratic:

$$\begin{aligned} f_1(x) &= 1 \\ f_2(x) &= x_1, \quad f_3(x) = x_2, \quad \dots, \quad f_{n+1}(x) = x_n \\ f_{n+2}(x) &= x_1^2, \quad f_{n+3}(x) = x_1 x_2, \quad \dots, \quad f_{2n+1}(x) = x_1 x_n \\ f_{2n+2}(x) &= x_2^2, \quad f_{n+3}(x) = x_2 x_3, \quad \dots, \quad f_{3n}(x) = x_2 x_n \\ &\dots \quad \dots \quad f_{\frac{(n+1)(n+2)}{2}} = x_n^2 \end{aligned}$$

$$J_f = [O_{n \times 1} \quad I_{n \times n} \quad H]$$

where H can be illustrated as:

$$\begin{aligned} n = 2 \quad : \quad H &= \begin{bmatrix} 2x_1 & x_2 & 0 \\ 0 & x_1 & 2x_2 \end{bmatrix} \\ n = 3 \quad : \quad H &= \begin{bmatrix} 2x_1 & x_2 & x_3 & 0 & 0 & 0 \\ 0 & x_1 & 0 & 2x_2 & x_3 & 0 \\ 0 & 0 & x_1 & 0 & x_2 & 2x_3 \end{bmatrix} \end{aligned}$$

2253

This class also support an user defined function.

```
def reg_model(x):
    ...
    return fx, jf
```

where, fx and jf are value of basis function and it's Jacobian at sample

point ‘x’.

$$\mathbf{fx} = \begin{bmatrix} f_1(x) & f_2(x) & \dots & f_l(x) \end{bmatrix}$$

$$\mathbf{jf} = \begin{bmatrix} \frac{\partial f_1(x)}{\partial x_1} & \frac{\partial f_2(x)}{\partial x_1} & \dots & \frac{\partial f_l(x)}{\partial x_1} \\ \frac{\partial f_1(x)}{\partial x_2} & \frac{\partial f_2(x)}{\partial x_2} & \dots & \frac{\partial f_l(x)}{\partial x_2} \\ \vdots & \vdots & \ddots & \vdots \\ \frac{\partial f_1(x)}{\partial x_n} & \frac{\partial f_2(x)}{\partial x_n} & \dots & \frac{\partial f_l(x)}{\partial x_n} \end{bmatrix}$$

- `corr_model`:
A function or string defining the correlation among the covariates of model. It explains the how similar are two points. There are six pre-defined correlation model inside the class i.e. ‘Exponential’, ‘Gaussian’, ‘Linear’, ‘Cubic’, ‘Spherical’ and ‘Spline’.

$$\mathcal{R}(\theta, s, x) = \prod_{j=1}^n \mathcal{R}_j(\theta, s_j - x_j)$$

Name	$\mathcal{R}_j(\theta, d_j)$
Exponential	$\exp(-\theta_j d_j)$
Gaussian	$\exp(-\theta_j d_j^2)$
Linear	$\max\{0, 1 - \theta_j d_j \}$
Spherical	$1 - 1.5\zeta_j + 0.5\zeta_j^3$
Cubic	$1 - 3\zeta_j^2 + 2\zeta_j^3$
Spline	$\xi(\zeta_j)(11), \quad \zeta_j = d_j $

Predefined correlation functions. Note: $d_j = s_j - x_j$ and $\zeta_j = \min\{1, \theta_j |d_j|\}$ for Spherical and Cubic correlation functions

$$\xi(\zeta_j) = \begin{cases} 1 - 15\zeta_j^2 + 30 * \zeta_j^3 & \text{for } 0 \leq \zeta_j \leq 0.2 \\ 1.25(1 - \zeta_j)^3 & \text{for } 0.2 \leq \zeta_j \leq 1 \\ 0 & \text{for } \zeta_j \geq 1 \end{cases} \tag{11}$$

This class also support an user defined function.

```
def corr_model(x, s, params, dt, dx):
    ...
    if dt:
        return rx, drdt
    if dx:
        return rx, drdx
    return rx
```

where ‘rx’ is an array defining the correlation matrix between ‘x’ and ‘s’. ‘drdt’ and ‘drdx’ are derivative of correlation matrix w.r.t hyperparameter (θ) and sample space (x).

$$\begin{aligned} \text{rx}_{ij} &= \prod_{k=1}^n \mathbf{R}_k(x_{ik} - s_{jk}) \\ \text{drdt}_{ijk} &= \frac{\partial \text{rx}_{ij}}{\partial \theta_k} \\ \text{drdx}_{ijk} &= \frac{\partial \text{rx}_{ij}}{\partial x_k} \end{aligned}$$

- 2257 • **corr_model_params:**
 2258 A numpy array of size $1 \times n$ specifying the starting point of hyper-
 2259 paramters for Maximum Likelihood Estimator. Default value is an array
 2260 of all ones.
- 2261 • **op:**
 2262 Indicator to solve MLE problem or not. If ‘True’, this class uses
 2263 `scipy.optimize.fmin_l_bfgs_b` to solve optimization problem. It is a
 2264 gradient-based optimization algorithm and uses **corr_model_params** as
 2265 initial point for optimization problem. If ‘False’, **corr_model_params**
 2266 will be directly use as hyperparamters. Default: ‘True’.
- 2267 • **n_opt:**
 2268 An integer specifying the number of times to estimate maximum likeli-
 2269 hood estimator with different random starting points. Default value is
 2270 assigned as 1.
- 2271 • **bounds:**
 2272 An array or list of size $2 \times n$, specifying the bounds on hyperparameters.

2273 These bounds are used to generate new random starting points, while
2274 estimating maximum likelihood solution. Random samples are generated
2275 using log-uniform distribution.

2276 *Krig Methods:*

2277 • **interpolate:**

2278 A function which takes samples and returns the value of surrogate model
2279 at the sample. If 'dy' is True, then this function returns value of surrogate
2280 model and mean square error at the sample.

```
2281       K = Krig(samples=S, values=Y, reg_model='Linear',  
2282                corr_model='Gaussian')  
2283       y, mse = K.interpolate(x, dy=True)
```

2284 • **jacobian:**

2285 A function which takes samples and returns the gradient of surrogate
2286 model at the samples.

```
2287       K = Krig(samples=S, values=Y, reg_model='Linear',  
2288                corr_model='Gaussian')  
2289       y_grad = K.jacobian(x)
```

2290 **Examples:**

2291 Two examples illustrating the use of the **Krig** class are provided in the follow-
2292 ing Jupyter scripts.

2293 • **Krig_Example1.ipynb:**

2294 In this example, the **STS** is used to generate 20 samples from a 1-D
2295 gamma probability distribution. The function values are evaluated us-
2296 ing **RunModel**. Kriging class is used to create an approximate surro-
2297 gate model using linear regression model and gaussian correlation model.
2298 Then plot is shown to compare the actual and surrogate model.

2299 • **Krig_Example2.ipynb:**

2300 In this example, the **STS** is used to generate 196 samples from a 2-D
2301 uniform probability distribution. Kriging class is used to create an ap-
2302 proximate surrogate model using quadratic regression model and expo-
2303 nential correlation model. Then 3-D plots show the comparison between
2304 the actual and surrogate model.

- 2305 • Krig_Example3.ipynb:
2306 This example illustrate the use of user-defined regression and correla-
2307 tion model. `reg_model` and `corr_model` are functions instead of strings,
2308 which uses pre-defined models.

2309 5.6 StochasticProcess Module

2310 The **StochasticProcess** module consists of classes and functions to generate
2311 samples of Stochastic Processes from Power Spectrum, Bispectrums and Auto-
2312 correlation Functions. The generated Stochastic Processes can be transformed
2313 into other random variables. We can import the module into a Python script
2314 with the following command

```
2315     from UQpy import StochasticProcess
```

2316 The **StochasticProcess** module has the following classes, each corresponding
2317 to a different method:

2318	Class	Method
	SRM	Spectral Representation Method
	BSRM	Bispectral Representation Method
	KLE	Karhunen Louve Expansion
	Translate	Translate Gaussian into Non-Gaussian
	Inverse_Translate	Translates Non-Gaussian into Gaussian

2319 Each class can be imported individually into a python script. For example,
2320 the **SRM** class can be imported to a script using the following command:

```
2321     from UQpy.StochasticProcess import SRM
```

2322 The following subsections describe each class, their respective inputs and at-
2323 tributes, and their use.

2324 5.6.1 UQpy.StochasticProcess.SRM (Coming in V2.0)

2325 **SRM** is a class for generating Stochastic Processes by Spectral Representation
2326 Method from a prescribed Power Spectral Density Function. The **SRM** class is
2327 imported using the following command:

```
2328     from UQpy.StochasticProcess import SRM
```

2329 The attributes of the **SRM** class are listed below:

SRM Class Attribute Definitions			
Attribute	Input/Output	Required	Optional
nsamples	Input	★	
S	Input	★	
dw	Input	★	
nt	Input	★	
nw	Input	★	
case	Input	★	
samples	Output		

Description of SRM Class Attributes:

Input Attributes:

- **nsamples:**
A scalar integer value defining the the number of samples of the Stochastic Process to be generated.
- **S:**
A numpy array defining the Power Spectral Density to be used for generation of the Stochastic Processes.
- **dw:**
The length of the frequency discretisation to be used for the generation of the Stochastic Processes.
- **nt:**
Specifies the number of time discretisations of the generated Stochastic Processes.
- **nw:**
Specifies the number of frequency discretisations of the Power Spectrum.
- **case:**
A String specifying if it is a univariate or multivariate Stochastic Process. Acceptable values are 'uni' for one variable case and 'multi' for multi variable case.

2357 *Output Attributes:*

2358 • **samples:**

2359 A numpy array of samples following the Power Spectral Density.

2360 **Examples:**

2361 A bunch of example files illustrating the use of the **SRM** class are provided:

2362 • **SRM_1D_1V.ipynb:**

2363 In this example, one-dimensional uni-variate Stochastic Processes are
2364 generated.

2365 • **SRM_1D_mV.ipynb:**

2366 In this example, one-dimensional multi-variate Stochastic Processes are
2367 generated.

2368 • **SRM_nD_1V.ipynb:**

2369 In this example, n-dimensional uni-variate Stochastic Processes are gen-
2370 erated.

2371 • **SRM_nD_mV.ipynb:**

2372 In this example, n-dimensional multi-variate Stochastic Processes are
2373 generated.

2374 5.6.2 `UQpy.StochasticProcess.BSRM` (Coming in V2.0)

2375 **BSRM** is a class for generating Stochastic Processes by BiSpectral Representa-
2376 tion Method from a prescribed Power Spectral Density Function and a Bis-
2377 pectral Density Function. The **BSRM** class is imported using the following
2378 command:

2379 `from UQpy.StochasticProcess import BSRM`

2380 The attributes of the **BSRM** class are listed below:

BSRM Class Attribute Definitions			
Attribute	Input/Output	Required	Optional
nsamples	Input	★	
S	Input	★	
B	Input	★	
2381 dt	Input	★	
dw	Input	★	
nt	Input	★	
nw	Input	★	
samples	Output		

2382 **Description of BSRM Class Attributes:**

2383

2384 *Input Attributes:*

2385 • **nsamples:**

2386 A scalar integer value defining the the number of samples of the Stochas-
2387 tic Process to be generated.

2388 • **S:**

2389 A numpy array defining the Power Spectral Density to be used for
2390 generation of the Stochastic Processes.

2391

2392 • **B:**

2393 A numpy array defining the BiSpectral Density to be used for generation
2394 of the Stochastic Processes.

2395

2396 • **dt:**

2397 The length of the time discretisation to be used for the generation of
2398 the Stochastic Processes.

2399

2400 • **dw:**

2401 The length of the frequency discretisation to be used for the generation
2402 of the Stochastic Processes.

2403

2404 • **nt:**

2405 Specifies the number of time discretisations of the generated Stochastic
2406 Processes.

2407

2408 • **nw:**

2409 Specifies the number of frequency discretisations of the Power Spectrum.

2410

2411 *Output Attributes:*

2412 • **samples:**

2413 A numpy array of samples generated by the BiSpectral Representation
2414 Method.

2415 **Examples:**

2416 Example files illustrating the use of the **BSRM** class have been provided:

2417 • **BSRM_1D.ipynb:**

2418 In this example, one-dimensional Stochastic Processes are generated by
2419 BSRM method.

2420 • **BSRM_nD.ipynb:**

2421 In this example, n-dimensional Stochastic Processes are generated by
2422 BSRM method.

2423 **5.6.3 UQpy.StochasticProcess.KLE (Coming in V2.0)**

2424 KLE is a class for generating Stochastic Processes by Karhunen Louve Expansion from a prescribed Autocorrelation Function. The **BSRM** class is imported using the following command:

2427 `from UQpy.StochasticProcess import KLE`

2428 The attributes of the KLE class are listed below:

2429

KLE Class Attribute Definitions			
Attribute	Input/Output	Required	Optional
nsamples	Input	★	
R	Input	★	
samples	Output		

2430 **Description of KLE Class Attributes:**

2431

2432 *Input Attributes:*

2433 • **nsamples:**

2434 A scalar integer value defining the the number of samples of the Stochastic Process to be generated.
2435

2436 • **R:**

2437 A numpy array defining the Autocorrelation Function to be used for
2438 generation of the Stochastic Processes.

2439

2440 *Output Attributes:*

2441 • **samples:**

2442 A numpy array of samples generated by the Karhunen Louve Expansion.

2443 **Examples:**

2444 An example files illustrating the use of the `KLE` class have been provided:

2445 • `KLE.ipynb`:

2446 In this example, Stochastic Processes are generated by Karhunen Louve
2447 Expansion method.

2448 5.6.4 `UQpy.StochasticProcess.Translation` (Coming in V2.0)

2449 `Translate` is a class for translating Gaussian Stochastic Processes to Non-
2450 Gaussian Stochastic Processes. This class returns the non-Gaussian samples
2451 along with the distorted Aurocorrelated Function. The `Translate` class is
2452 imported using the following command:

2453 `from UQpy.StochasticProcess import Translate`

2454 The attributes of the `Translate` class are listed below:

Translate Class Attribute Definitions			
Attribute	Input/Output	Required	Optional
<code>samples_g</code>	Input	★	
<code>R_g</code>	Input	★	
<code>marginal</code>	Input	★	
<code>params</code>	Input	★	
<code>samples_ng</code>	Output		
<code>R_ng</code>	Output		

2456 Description of Translate Class Attributes:

2457

2458 *Input Attributes:*

2459 • `samples_g`:

2460 Numpy array of Gaussian samples to be translated into specified non-
2461 Gaussian samples.

2462 • `R_g`:

2463 Numpy array providing the Autocorrelation Function of the Gaussian
2464 Stochastic Processes.

2465

2466 • `marginal`:

2467 The name of the marginal distribution to which to be translated. It
2468 must follow the format discussed in the Distributions module.(Examples
2469 Jupyter script may be referred for further coherence)

- **params:**
The parameters of the marginal distribution to which to be translated. It must follow the format discussed in the Distributions module.(Examples Jupyter script may be referred for further coherence)

Output Attributes:

- **samples_ng:**
Numpy array of the translated Non-Gaussian samples.
- **R_ng:**
Numpy array of the distorted Non-Gaussian Autocorrelation Function.

Examples:

An example files illustrating the use of the **Translate** class have been provided:

- **Translate.ipynb:**
In this example, a Gaussian Stochastic Process has been translated into a Uniform[0, 1] process.

5.6.5 UQpy.StochasticProcess.InverseTranslation (Coming in V2.0)

Inverse_Translate is a class for translating Non-Gaussian Stochastic Processes back to Standard Gaussian Stochastic Processes. This class returns the non-Gaussian samples along with the distorted Aurocorrelated Function. The **Translate** class is imported using the following command:

```
from UQpy.StochasticProcess import InverseTranslation
```

The attributes of the **Translate** class are listed below:

Translate Class Attribute Definitions			
Attribute	Input/Output	Required	Optional
samples_ng	Input	★	
R_ng	Input	★	
marginal	Input	★	
params	Input	★	
samples	Output		

Description of BSRM Class Attributes:

Input Attributes:

2495 • **samples_g:**
2496 Numpy array of non-Gaussian samples to be translated into standard
2497 Gaussian samples.

2498 • **R_ng:**
2499 Numpy array providing the Autocorrelation Function of the non-
2500 Gaussian Stochastic Processes.
2501

2502 • **marginal:**
2503 The name of the marginal distribution the Stochastic Process currently
2504 follows. It must follow the format discussed in the Distributions mod-
2505 ule.(Examples Jupyter script may be referred for further coherence)

2506 • **params:**
2507 The parameters of the marginal distribution the Stochastic Process cur-
2508 rently follows. It must follow the format discussed in the Distributions
2509 module.(Examples Jupyter script may be referred for further coherence)

2510 *Output Attributes:*

2511 • **samples_g:**
2512 Numpy array of the standard Gaussian samples.

2513 • **R_ng:**
2514 Numpy array of the Gaussian Autocorrelation Function.

2515 **Examples:**
2516 An example files illustrating the use of the **Inverse.Translate** class have been
2517 provided:

2518 • **Inverse.Translate.ipynb:**
2519 In this example, a non-Gaussian Stochastic Process is translated into a
2520 standard Gaussian Stochastic Process.

2521 5.7 Transformations

	Class	Method
	Correlate	Induces correlation
2522	Decorrelate	Removes correlation
	Nataf	Nataf transformation
	InvNataf	Inverse Nataf transformation

2523 5.7.1 UQpy.SampleMethods.Correlate

Correlate is a class for inducing correlation in independent standard normal random variables. This is done using the standard Cholesy method as follows. Let \mathbf{Y} denote an uncorrelated standard normal random vector and \mathbf{Z} denote a standard normal random vector with positive definite correlation matrix \mathbf{C}_Z . Perform the Cholesky decomposition of \mathbf{C}_Z such that:

$$\mathbf{C}_Z = \mathbf{U}\mathbf{U}^T \quad (12)$$

2524 where \mathbf{U} is a lower-triangular matrix.

Given the `nsamples × dimension` array, \mathbf{y} , of uncorrelated standard normal samples, the array \mathbf{z} of samples possessing correlation \mathbf{C}_Z is determined by:

$$\mathbf{z}^T = \mathbf{U}\mathbf{y}^T \quad (13)$$

2525 The **Correlate** class is imported using the following command:

2526 `from UQpy.SampleMethods import Correlate`

2527 The attributes of the **Correlate** class are listed below:

	Correlate Class Attribute Definitions			
	Attribute	Input/Output	Required	Optional
	<code>input_samples</code>	Input	★	
2528	<code>corr_norm</code>	Input	★	
	<code>dimension</code>	Input	★	★
	<code>samples_uncorr</code>	Output		
	<code>samples</code>	Output		

2529 A brief description of each attribute can be found in the table below:

2530

Correlate Class Attributes			
Attribute*	Type	Options	Default
input_samples	<i>ndarray/object</i>	SampleMethods object or User-defined array	
corr_norm	<i>ndarray</i>	User-defined array	
dimension	<i>integer</i>	Inherited from SampleMethods object or User-defined scalar	
samples_uncorr	<i>ndarray</i>		
samples	<i>ndarray</i>		

2531

* Note: If `input_samples` is a `SampleMethods` object, the `Correlate` object will inherit all attributes of that object.

2534

Detailed Description of Correlate Class Attributes:

2536

Input Attributes:

2538

- **input_samples:**
Contains the independent standard normal random samples on which to impose correlation.

2541

`input_samples` can be an object (instance of a `SampleMethods` class) or an array.

2544

If `input_samples` is an instance of a `SampleMethods` class, then the `Correlate` class inherits all of its attributes and the correlation is induced on the samples contained in the attribute `input_samples.samples`.

2549

If `input_samples` is a `numpy` array, then the correlation is induced directly on `input_samples`. The number of samples is given by `nsamples=input_samples.shape[0]`.

2553

2554

- **corr_norm:**
A `numpy` array containing the correlation matrix **C** for the random variables.

2557

2558 `corr_norm` must be a symmetric positive definite array of size
2559 `dimension × dimension` and satisfy:

2560 `corr_norm[i, j] = 1` for `i = j`.

2561 `0 < corr_norm[i, j] < 1` for `i ≠ j`.

2562 `corr_norm[i,j] = corr_norm[j,i]`

2563 • **dimension:**

2564 A scalar integer value defining the dimension of the random variables.

2565

2566 If `input_samples` is a `SampleMethods` object then `dimension`
2567 is not required since `input_samples` already has the attribute
2568 `input_samples.dimension`.

2569

2570 If `input_samples` is a `numpy` array, `dimension` must be specified.

2571 *Output Attributes:*

2572 • **samples_uncorr:**

2573 A `numpy` array of dimension `nsamples × dimension` containing the orig-
2574 inal uncorrelated standard normal samples.

2575 If `input_samples` is an array then `samples_uncorr=input_samples`.

2576

2577 if `input_samples` is a `SampleMethods` object, then
2578 `samples_uncorr=input_samples.samples`.

2579 • **samples:**

2580 A `numpy` array of dimension `nsamples × dimension` containing the cor-
2581 related standard normal samples with correlation defined in `corr_norm`.

2582 **Examples:**

2583 An example illustrating the use of the `Correlate` class is provided in the
2584 following Jupyter script.

2585 • **Correlate.ipynb:**

2586 In this example, 1000 2-dimensional standard normal samples are corre-
2587 lated according to a specified correlation matrix. The input samples are
2588 specified using both the `MCS` class and as a `numpy` array generated using
2589 `scipy.stats`.

2590 5.7.2 UQpy.SampleMethods.Decorrelate

Decorrelate is a class for removing correlation from a `nsamples×dimension` array, `z`, of standard normal random samples with correlation matrix `Cz`. This is performed by simply inverting the expression in Eq. (13) as:

$$\mathbf{y}^T = \mathbf{U}^{-1} \mathbf{z}^T \quad (14)$$

2591 to obtain the `nsamples×dimension` array, `y`, of uncorrelated standard
2592 normal samples.

2593

2594 The Decorrelate class is imported using the following command:

2595 `from UQpy.SampleMethods import Decorrelate`

2596 The attributes of the Decorrelate class are listed below:

Decorrelate Class Attribute Definitions			
Attribute	Input/Output	Required	Optional
input_samples	Input	★	
corr_norm	Input	★	
dimension	Input	★	★
samples_corr	Output		
samples	Output		

2598 A brief description of each attribute can be found in the table below:

2599

Decorrelate Class Attributes			
Attribute*	Type	Options	Default
input_samples	<i>ndarray/object</i>	Object of class <code>Correlate</code> or User-defined array	
corr_norm	<i>ndarray</i>	Inherited from <code>Correlate</code> object or User-defined array	
dimension	<i>integer</i>	Inherited from <code>Correlate</code> object or User-defined scalar	
samples_corr	<i>ndarray</i>		
samples	<i>ndarray</i>		

2601 * Note: If `input_samples` is a `Correlate` object, the `Decorrelate` object
2602 will inherit all attributes of that object.

2603

2604 **Detailed Description of Decorrelate Class Attributes:**

2605

2606 *Input Attributes:*

2607 • **input_samples:**

2608 Contains the correlated standard normal samples whose correlation will
2609 be removed.

2610

2611 `input_samples` can be an object (instance of the `Correlate` class) or a
2612 `numpy` array.

2613

2614 If `input_samples` is an instance of `Correlate`, then the `Decorrelate`
2615 class inherits all of its attributes and the decorrelation is performed on
2616 the attribute `input_samples.samples`.

2617

2618 If `input_samples` is a `numpy` array, then the decorrelation is performed
2619 directly on `input_samples`. The number of samples is given by
2620 `nsamples=input_samples.shape[0]`.

2621

2622 • **corr_norm:**

2623 A `numpy` array containing the correlation matrix **C** for the random
2624 variables.

2625

2626 If `input_samples` is an object of the `Correlate` class, then `corr_norm`
2627 is inherited this class.

2628

2629 If `input_samples` is a `numpy` array, then `corr_norm` must be specified.

2630

2631 `corr_norm` must be a symmetric positive definite array of size
2632 `dimension × dimension` and satisfy:

2633 $\text{corr_norm}[i, j] = 1$ for $i = j$.

2634 $0 < \text{corr_norm}[i, j] < 1$ for $i \neq j$.

2635 $\text{corr_norm}[i, j] = \text{corr_norm}[j, i]$

2636 • **dimension:**

2637 A scalar integer value defining the dimension of the random variables.

2638

2639 If `input_samples` is a `Correlate` object then `dimension` may not
 2640 be required since `input_samples` may already have the attribute
 2641 `input_samples.dimension`.

2642

2643 If `input_samples` is a numpy array, `dimension` must be specified.

2644 *Output Attributes:*

2645 • `samples_corr`:

2646 A numpy array of dimension `nsamples × dimension` containing the
 2647 original correlated samples.

2648

2649 If `input_samples` is an array then `samples_corr=input_samples`
 2650 and if `input_samples` is an object of the `Correlate` class then
 2651 `samples_corr=input_samples.samples`.

2652 • `samples`:

2653 A numpy array of dimension `nsamples × dimension` containing the un-
 2654 correlated standard normal samples.

2655 **Examples:**

2656 An example illustrating the use of the `Decorrelate` class is provided in the
 2657 following Jupyter script.

2658 • `Decorrelate.ipynb`:

2659 In this example, 1000 2-dimensional correlated standard normal samples
 2660 are generated using the `Correlate` class and using the `scipy.stats`
 2661 package. The samples from each are decorrelate using the `Decorrelate`
 2662 class.

2663 5.7.3 `UQpy.SampleMethods.InvNataf`

2664 `InvNataf` is a class for transforming standard normal random samples to
 2665 a prescribed non-Gaussian distribution using the inverse Nataf transformation.

2666

Theory

Let \mathbf{Z} denote an n -dimensional standard normal random vector and let $F_i(x_i), i = 1, \dots, n$ be the marginal cumulative distribution functions of the n correlated non-Gaussian random variables X_i . According to the Nataf transformation, the non-Gaussian random vector, \mathbf{X} , following $F_i(x_i)$ is defined component-wise through the transformation:

$$x_i = F_i^{-1}(\Phi(z_i)) \quad (15)$$

2667 where $\Phi(x)$ is the standard normal cumulative distribution function.

2668

When the random vector \mathbf{Z} has correlated components possessing correlation matrix $\mathbf{C}_{\mathbf{Z}}$ and correlation coefficients ρ_{ij} between components Z_i and Z_j , the transformation in Eq. (15) causes a so-called *correlation distortion* such that the correlation coefficient between the non-Gaussian variables X_i and X_j , denoted ξ_{ij} , is not equal to the correlation between the Gaussian variables ($\rho_{ij} \neq \xi_{ij}$). The non-Gaussian correlation coefficient, ξ_{ij} , can be determined from the Gaussian correlation coefficient, ρ_{ij} , through the following integral:

$$\xi_{ij} = \frac{1}{\sigma_{X_i} \sigma_{X_j}} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} (F_i^{-1}(\Phi(z_i)) - \mu_{X_i}) (F_j^{-1}(\Phi(z_j)) - \mu_{X_j}) \phi_2(z_i, z_j; \rho_{ij}) dz_i dz_j \quad (16)$$

2669 where $\phi_2(\cdot)$ is the joint Gaussian pdf.

When conducting probabilistic modeling using the inverse Nataf transformation (particularly when performing the first and second order reliability method FORM/SORM, see Section ??), it is useful to know the Jacobian of the transformation in Eq. (15). Let us rewrite Eq. (15) as:

$$F_i(x_i) = \Phi(z_i) \quad (17)$$

Taking the derivative of Eq. (17) yields:

$$\begin{aligned} \frac{\partial F_i}{\partial x_i} &= \frac{\partial}{\partial x_i} (\Phi(z_i)) \\ f_i(x_i) &= \frac{\partial \Phi(z_i)}{\partial x_i} \frac{\partial z_i}{\partial x_i} \\ f_i(x_i) &= \phi(z_i) \frac{\partial z_i}{\partial x_i} \end{aligned}$$

Rearranging this equation, we arrive at the Jacobian of the inverse Nataf transformation with components

$$J_{x_i, z_i} = \frac{\partial x_i}{\partial z_i} = \frac{\phi(z_i)}{f_i(x_i)} \quad (18)$$

The Jacobian of the inverse Nataf transformation is assembled as a diagonal matrix given by:

$$\mathbf{J}_{\mathbf{xz}} = \frac{\partial \mathbf{x}}{\partial \mathbf{z}} = \begin{bmatrix} \frac{\phi(z_i)}{f_i(x_i)} \end{bmatrix} \quad (19)$$

It is more common, in practice, to combine the steps of correlating the variables and mapping them to the non-Gaussian distribution through the inverse Nataf. In other words, letting \mathbf{y} denote an n -dimensional vector of uncorrelated standard normal random variables, we can express the Jacobian of the transformation from \mathbf{y} to \mathbf{x} by:

$$\mathbf{J}_{\mathbf{xy}} = \frac{\partial \mathbf{x}}{\partial \mathbf{y}} = \frac{\partial \mathbf{x}}{\partial \mathbf{z}} \frac{\partial \mathbf{z}}{\partial \mathbf{y}} \quad (20)$$

where, by applying Eqs. (13) and (19), we see that:

$$\mathbf{J}_{\mathbf{xy}} = \frac{\partial \mathbf{x}}{\partial \mathbf{y}} = \mathbf{U} \begin{bmatrix} \phi(z_i) \\ f_i(x_i) \end{bmatrix} \quad (21)$$

2670 where \mathbf{U} is the lower triangular matrix resulting from the Cholesky decomposition of $\mathbf{C}_{\mathbf{z}}$ in Eq. (12).
 2671

2672 The Jacobian in Eq. (21), which combines the correlation and inverse
 2673 Nataf steps, is the one computed by the `InvNataf` class.

2674

2675 Using the `InvNataf` Class

2676 The `InvNataf` class is imported using the following command:

2677 `from UQpy.SampleMethods import InvNataf`

2678 The attributes of the `InvNataf` class are listed below:

InvNataf Class Attribute Definitions			
Attribute	Input/Output	Required	Optional
<code>input_samples</code>	Input		★
<code>corr_norm</code>	Input	★	
<code>dist_name</code>	Input	★	
2679 <code>dist_params</code>	Input	★	
<code>dimension</code>	Input	★	★
<code>samplesN01</code>	Output		
<code>samples</code>	Output		
<code>corr</code>	Output		
<code>jacobian</code>	Output		

2680 A brief description of each attribute can be found in the table below:

2681

InvNataf Class Attributes			
Attribute	Type	Options	Default
<code>input_samples</code>	<i>ndarray/object</i>	<code>SampleMethods</code> object or User-defined array	None
<code>corr_norm</code>	<i>ndarray</i>	Inherited from <code>SampleMethods</code> object or User-defined array	Identity Matrix $\mathbf{I}_{\text{dimension}}$
<code>dimension</code>	<i>integer</i>	Inherited from <code>SampleMethods</code> object or User-defined integer	
<code>dist_name</code>	<i>function/string list</i>	<code>name</code> attribute from <code>Distributions</code> class See Section 6.1	
<code>dist_params</code>	<i>ndarray list</i>	See Section 6.1	
<code>samplesN01</code>	<i>ndarray</i>		
<code>samples</code>	<i>ndarray</i>		
<code>corr</code>	<i>ndarray</i>		
<code>jacobian</code>	<i>ndarray list</i>		

2682

2683

Detailed Description of InvNataf Class Attributes:

2684

2685

Input Attributes:

2686

- `input_samples`:

2687

Contains the samples to be transformed. The samples need to be standard normal samples i.e $\sim N(0, 1)$.

2688

2689

2690

`input_samples` can be a `SampleMethods` object or a `nsamples × dimension` numpy array. The inverse Nataf transformation is applied to the `samplesN01` object. Depending on the type of `input_samples`, `samplesN01` is assigned as follows:

2691

2692

2693

2694

- If `input_samples` is a `SampleMethods` object, then the `InvNataf` class inherits all the attributes of that object and `samplesN01 = input_samples.samples`

2695

2696

2697

2698

- If `input_samples` is an array, then `samplesN01 = input_samples`.

2699

2700

If `input_samples` is not provided, then `InvNataf` calculates the correlation distortion of the standard normal correlation matrix `corr_norm` from Eq. (16).

2701

2702

2703

2704

The default value of `input_samples` is None.

2705

2706 • **dimension:**
2707 A scalar integer value defining the dimension of the random variables.
2708
2709 If `input_samples` is a `SampleMethods` object, then `dimension` may
2710 not be required since `input_samples` may already have the attribute
2711 `input_samples.dimension`.
2712
2713 If `input_samples` is a numpy array, `dimension` must be specified.

2714 • **corr_norm:**
2715 A numpy array containing the correlation matrix **C** for the standard
2716 normal random variables.
2717
2718 `corr_norm` must be a symmetric positive definite array of size
2719 `dimension × dimension` and satisfy:

2720 `corr_norm[i, j] = 1` for `i = j`.
2721 `0 < corr_norm[i, j] < 1` for `i ≠ j`.
2722 `corr_norm[i, j] = corr_norm[j, i]`

2723 If `input_samples` is an object of type `Correlate` then `corr_norm` is
2724 inherited from this object.
2725
2726 The default value of `corr_norm` is the `dimension × dimension` identity
2727 matrix **I_{dimension}**.
2728

2729 • **dist_name:**
2730 Specifies the name of the marginal distribution that each transformed
2731 random variable.
2732
2733 `dist_name` may be a string or a list of strings of length `dimension`.
2734
2735 For each dimension `i`, `dist_name[i]` must be a string specifying a
2736 distribution defined in the `Distributions` module (see Sec. 6.1). To
2737 use a custom distribution, set `dist_name[i] = 'custom_dist'` to use the
2738 custom distribution assignment option in the `Distributions` module
2739 (again, see Sec. 6.1).
2740

2741 If `dist_name` is a string (or a list of length one) and `dimension > 1`,
 2742 then `dist_name` is converted into a list of length `dimension` with each
 2743 component having identical distribution name.
 2744

2745 `dist_name` must be specified. There is no default value.

2746 • `dist_params`:
 2747 Specifies the parameters for each marginal distribution in `dist_name` as
 2748 defined in the `Distributions` module (see Sec. 6.1).
 2749

2750 Each set of parameters is defined as a `numpy` array. `dist_params` is a
 2751 list of arrays, with each item in the list corresponding to the associated
 2752 random variable.
 2753

2754 If `dist_params` is an array (or a list of length one), then `dist_params`
 2755 is converted to a list of length `dimension` with each component having
 2756 the same parameters.
 2757

2758 `dist_params` must be specified. There is no default value.

2759 *Output Attributes:*

2760 • `samplesN01`:
 2761 A `numpy` array of dimension `nsamples × dimension` containing the
 2762 correlated or uncorrelated standard normal samples that have have
 2763 been transformed.
 2764

2765 If `input_samples = None`, `samplesN01` is not returned.
 2766

2767 If `input_samples` is a `SampleMethods` object, then `samplesN01`
 2768 = `SampleMethods.samples`. If `input_samples` is an array then
 2769 `samplesN01 = input_samples`.
 2770

2771 • `samples`:
 2772 A `numpy` array of dimension `nsamples × dimension` containing the
 2773 correlated or uncorrelated transformed samples follwing the prescribed
 2774 distribution.
 2775

2776 If `input_samples = None`, `samples` is not returned.
 2777

- 2778 • **corr:**
 2779 A `numpy` array containing the transformed/distorted correlation matrix.
 2780
 2781 If `corr_norm = None` or `corr_norm = I`, where **I** is the identity matrix,
 2782 then `corr = corr_norm = I`.
 2783
- 2784 • **jacobian:**
 2785 A list of `numpy` arrays containing the Jacobian of the transformation
 2786 evaluated at each sample.
 2787

2788 **Examples:**
 2789 Three examples illustrating the use of the `Nataf` class are provided in the
 2790 following Jupyter scripts.

- 2791 • **InvNataf - Example 1.ipynb:**
 2792 In this example, the `InvNataf` class is used in order to transform 1000
 2793 samples of 2 uncorrelated standard normal variables to a lognormal and
 2794 a gamma distribution. The example illustrates the transformation for
 2795 samples drawn using the `MCS` class and for samples specified as a `numpy`
 2796 array.
- 2797 • **InvNataf - Example 2.ipynb:**
 2798 In this example, the `InvNataf` class is used in order to transform 1000
 2799 samples of 2 correlated standard normal variables to a lognormal and
 2800 a gamma distribution. The example illustrates the transformation for
 2801 samples drawn using the `MCS` class and correlated using the `Correlate`
 2802 class and for samples specified as a `numpy` array.
- 2803 • **InvNataf - Example 3.ipynb:**
 2804 In this example, the `InvNataf` class is used to calculate the correlation
 2805 distortion for the transformation of two correlated random variables from
 2806 a standard normal to a lognormal distribution.

2807 5.7.4 `UQpy.SampleMethods.Nataf`

2808 **Nataf** is a class for transforming non-Gaussian random variables to equiva-
 2809 lent standard normal space. The `Nataf` class is imported using the following
 2810 command:

2811 `from UQpy.SampleMethods import Nataf`

2812 The attributes of the Nataf class are listed below:

2813

Nataf Class Attribute Definitions			
Attribute	Input/Output	Required	Optional
input_samples	Input	★	★
dimension	Input	★	★
corr	Input	★	
dist_name	Input	★	★
dist_params	Input	★	★
samplesNG	Output		
samples	Output		
corr_norm	Output		
jacobian	Output		

2814 A brief description of each attribute can be found in the table below:

2815

Nataf Class Attributes			
Attribute	Type	Options	Default
input_samples	<i>ndarray/object</i>	Attribute of class MCS, LHS, STS, Correlate, Nataf or User-defined array	None
corr	<i>ndarray</i>	Attribute of class Nataf or User-defined array	
dimension	<i>integer</i>	Attribute of class MCS, LHS, STS, Correlate, Nataf or User-defined scalar	
dist_name	<i>function/string list</i>	See Distributions Module or User-defined function	
dist_params	<i>ndarray list</i>		
samplesNG	<i>ndarray</i>		
samples	<i>ndarray</i>		
corr_norm	<i>ndarray</i>		
jacobian	<i>ndarray list</i>		

2816 Detailed Description of Nataf Class Attributes:

2817

2818 *Input Attributes:*

- 2819 • **input_samples:**

2820 Contains the samples to be transformed to standard normal samples.

2821

2822 `input_samples` can be an object of type `MCS`, `LHS`, `STS`, `Correlate`,
2823 `InvNataf` or a numpy array.
2824

2825 If `input_samples` is an object of type `MCS`, `LHS`, `STS`, `Correlate`,
2826 `Nataf`, then the `InvNataf` class inherits all the attributes of the class
2827 and the transformation is performed to the attribute `.samples` of the
2828 class.
2829

2830 If `input_samples` is an array then the transformation is performed
2831 directly to the `input_samples`. The number of samples is given by
2832 `nsamples=input_samples.shape[0]`.
2833

2834 If `input_samples` is not provided then class `Nataf` calculates the
2835 correlation matrix `corr_norm` in the standard normal space.
2836

2837 The default value of `input_samples` is `None`.
2838

- 2839 • **dimension:**
2840 A scalar integer value defining the dimension of the random variables.
- 2841 • **corr:**
2842 A numpy array showing the correlation coefficients between the
2843 non-Gaussian random variables.
2844

2845 `corr` must be an array of size `dimension × dimension` and satisfy:
2846

$$2847 \quad \text{corr}[i, j] = 1 \text{ for } i = j.$$

$$2848 \quad \text{corr}[i, j] < 1 \text{ for } i \neq j.$$

2849

2850 if `input_samples` is an object of type `Nataf` then `corr` is an attribute
2851 of this class.
2852

2853 if `input_samples` is an object of type `MCS`, `LHS`, `STS` then `corr` is set
2854 to be the identity matrix `I_dimension`.
2855

2856 • **dist_name:**
2857 Defines the name of the marginal distribution that each standard
2858 normal random variable will be transformed to.
2859

2860 **dist_name** may be a string, a function, or a list of strings/functions.
2861

2862 If **dist_name[i]** is a string, the distribution is matched with one of the
2863 available functions in the **Distributions** module (see Sec. 6.1) or the
2864 ‘custom_dist.py’ (again see Sec. 6.1).
2865

2866 if **dist_name[i]** is a function, it must be defined in the user’s Python
2867 script and passed directly as a function.
2868

2869 **dist_name** can contain an arbitrary combination of strings and functions.
2870

2871 If **dist_name** is a string or function (or a list of length one) and
2872 **dimension > 1**, then **dist_name** is converted into a list of length
2873 **dimension** with each variable having the distribution.
2874

2875 if **data** is not an object of type **MCS**, **LHS**, **STS**, **InvNataf** then
2876 **dist_name** must be specified. There is no default value.

2877 • **dist_params:**
2878 Specifies the parameters for each marginal distribution in **dist_name**.
2879

2880 Each set of parameters is defined as a numpy array. **dist_params** is a
2881 list of arrays, with each item in the list corresponding to the associated
2882 random variable.
2883

2884 If **dist_params** is an array (or a list of length one), then **dist_params**
2885 is converted to a list of length **dimension** with each variable having the
2886 same parameters.
2887

2888 if **input_samples** is not an object of type **MCS**, **LHS**, **STS**, **InvNataf**
2889 then **dist_params** must be specified. There is no default value.

2890 *Output Attributes:*

2891 • **samplesNG:**
2892 A numpy array of dimension `nsamples × dimension` containing the
2893 correlated or uncorrelated non-Gaussian samples. It is an output of the
2894 class only if `data` is not `None`.
2895
2896 If `input_samples` is an object of type `MCS`, `LHS`, `STS`, `Correlate`,
2897 `InvNataf` then `samplesNG .samples`. If `input_samples` is an array
2898 then `samplesNG=input_samples`.
2899
2900 • **samples:**
2901 A numpy array of dimension `nsamples × dimension` containing the
2902 correlated or uncorrelated standard normal samples. It is an output of
2903 the class only if `input_samples` is not `None`.
2904
2905 • **corr_norm:**
2906 A numpy array containing the correlation matrix in the standard
2907 normal space.
2908
2909 if `data` is an object of type `MCS`, `LHS`, `STS`, `Correlate` then `corr =`
2910 `corr_norm = I.dimension`.
2911
2912 • **jacobian:**
2913 A list containing the jacobian of the transformation for each sample as
2914 an numpy array.
2915
2916 **Examples:**
2917 An example illustrating the use of the `Correlate` class is provided in the
2918 following Jupyter script.
2919 • **Nataf - Example 1.ipynb:**
2920 In this example, `Nataf` class is used in order to transform 2 correlated
2921 lognormal variables to two standard normal random variables.
2922 • **Nataf - Example 2.ipynb:**
2923 In this example, `Nataf` class is used to perform the Iterative Translation
2924 Approximation Method (ITAM) [16] to estimate the underlying Gaussian
2925 correlation from known values of the correlation for lognormal random
2926 variables.

2927 **6 Support Modules**

2928 The modules detailed in Section 5 form the core of `UQpy` and its primary capa-
2929 bilities. In support of these primary modules are two additional modules that
2930 provide capabilities that are generally used throughout the primary modules.
2931 These two support modules are described herein.

2932 6.1 Distributions Module

2933 The `Distributions` module is the structure through which probability dis-
 2934 tributions and their related operations are defined in `UQpy`. This includes
 2935 functions for computing probability densities, cumulative distributions and
 2936 their inverses, moments, the logarithms of the probability densities as well as
 2937 parameter estimates for data from common distribution types.

2938 The `Distributions` module is imported in a Python script using the fol-
 2939 lowing command:

```
2940 from UQpy import Distributions
```

2941 The `Distributions` module contains three classes: the `Distribution` class,
 2942 the `SubDistribution` class, and the `Copula` class. The `Distribution` class is
 2943 the parent class of the module, which calls the `SubDistribution` and `Copula`
 2944 classes as necessary to construct a `Distribution` object. The `Distributions`
 2945 module also allows the user to define a custom distribution.

2946 Distributions in `UQpy` can generally be categorized in one of three types:
 2947 1. Marginal distributions for a single random variable; 2. Joint distributions
 2948 with independent random variables; 3. Joint distributions with dependent
 2949 random variables. The user can define a probability distribution object by
 2950 providing a name (see supported distributions in `SubDistribution` class or
 2951 custom distribution) and a dependency structure through the `Copula` class
 2952 (optional).

2953 6.1.1 `UQpy.Distributions.Distribution`

2954 The `Distribution` class can be imported using the following command:

```
2955 from UQpy.Distributions import Distribution
```

2956 The `Distribution` class possesses the following attributes:

2957

Distribution Class Attribute Definitions			
Attribute	Input/Output	Type	Required
dist_name	Input	<i>string/list</i>	*
copula	Input	<i>string</i>	

2958 Detailed Description of Distribution Class Attributes:

2959

2960 *Input Attributes:*

- 2961 • **dist_name:**
2962 A *string* or a *list* of *strings* designating the distribution name (avail-
2963 able distributions are shown in Table 3 below) and the distribution type
2964 (univariate/multivariate).
 - 2965 – If **dist_name** is a *string* → univariate distribution.
 - 2966 – If **dist_name** is a *list* → multivariate distribution.
- 2967 **dist_name** must be specified. **Distribution** does not have a default
2968 distribution type.
- 2969 • **copula:**
2970 Defines the dependency between random variables and in order to use it
2971 the **dist_name** should be given as a *list*. The available copulas are shown
2972 in Section 6.1.3 below.
- 2973 **copula** is optional. The default **copula** value is **None**.

2974 6.1.2 UQpy.Distributions.SubDistribution

2975 The **SubDistribution** class is used to invoke various methods (functions)
2976 for specified distributions. In general, **SubDistribution** class will not be
2977 invoked directly by the user but only through the **Distribution** class. With
2978 the exception of the custom distribution, the **SubDistribution** class simply
2979 repackages certain methods from the **scipy.stats** package in a way that is
2980 convenient for constructing distribution objects in UQpy.

2981
2982 The **SubDistribution** class, has the following attribute:

SubDistribution Class Attribute Definitions			
Attribute	Input/Output	Type	Required
dist_name	Input	<i>string</i>	*

2984 and the following methods:

SubDistribution Class Methods	
Method	Type
pdf	<i>function</i>
rvs	<i>function</i>
cdf	<i>function</i>
icdf	<i>function</i>
log_pdf	<i>function</i>
fit	<i>function</i>
moments	<i>function</i>

2988 The `SubDistribution` class possesses the following methods (functions): `pdf`,
 2989 `cdf`, `icdf`, `rvs`, `moments`, `log_pdf`, `fit`. Each method is detailed below.

2990 • **pdf:**

2991 A function that returns the probability density function at a specified
 2992 value or values x . Note that the parameters of the distribution must be
 2993 passed into the `pdf` function.

2994 If the distribution is univariate (or the special case of multivariate nor-
 2995 mal) the function is called as follows:

2996 `Distribution(dist_name).pdf(x, params)`

2997 If the distribution is multivariate the function is called as follows:

2998 `Distribution([dist_name_1,...]).pdf(x, [params_1,...])`

2999 Note that `[params_1, params_2, ...]` correspond to distribution mod-
 3000 els `[dist_name_1, dist_name_2,...]`. In this case, the output of the `pdf`
 3001 function is the product of the marginal `pdfs`

$$\prod_i \text{Distribution}(\text{dist_name_i}).\text{pdf}(x[:, i], \text{params_i})$$

3002 where x is a *numpy array* and `params/params_i` is given as a *list*.

3003 • **rvs:**

3004 A function that draws random samples from the specified distribution.
 3005 Note that the parameters of the distribution must be passed into the `rvs`
 3006 function and the number of samples (`nsamples`) must be specified.

3007 For a univariate distribution the function is called as follows:

3008 `Distribution(dist_name).rvs(params, nsamples)`

3009 If the distribution is multivariate the function is called as follows:

3010 `Distribution([dist_name_1,...]).rvs([params_1,...], nsamples)`

3011 In this case the output vector is defined as

$$x[:, i] = \text{Distribution}(\text{dist_name_i}).\text{rvs}(\text{params_i}, \text{nsamples})$$

3012 Here, `params/params_i` is given as a *list* and `nsamples` is an *integer*.

3013 • **cdf:**
3014 A function that returns the cumulative distribution function at a specified
3015 value x . Note that the parameters of the distribution must be passed into the
3016 **cdf** function.

3017 For a univariate distribution the function is called as follows:

3018 `Distribution(dist_name).cdf(x,params)`

3019 If the distribution is multivariate the function is called as follows:

3020 `Distribution([dist_name_1,...]).cdf(x, [params_1,...])`

3021 In the multivariate case the output is a *list* with entries the val-
3022 ues of **cdf** calculated at x for every distribution model defined in
3023 `[dist_name_1,dist_name_2,...]`.

3024 Here, x is a *numpy array* and $params/params_i$ is given as a *list*.

3025 • **icdf:**
3026 A function that returns the inverse cumulative distribution function at a spec-
3027 ified value or values $x \in [0, 1]$. Note that the parameters of the distribution
3028 must be passed into the **icdf** function.

3029 For a univariate distribution the function is called as follows:

3030 `Distribution(dist_name).icdf(x,params)`

3031 If the distribution is multivariate the function is called as follows:

3032 `Distribution([dist_name_1,...]).icdf(x, [params_1,...])`

3033 In the multivariate case the output is a *list* with entries the val-
3034 ues of **icdf** calculated at x for every distribution model defined in
3035 `[dist_name_1,dist_name_2,...]`.

3036 Here, x is a *numpy array* and $params/params_i$ is given as a *list*.

3037 • **log_pdf:**
3038 A function that returns the logarithm of the probability density function at a
3039 specified value or values x . Note that the parameters of the distribution must
3040 be passed into the **log_pdf** function.

3041 If the distribution is univariate the function is called as follows:

3042 `Distribution(dist_name).log_pdf(x,params)`

3043 If the distribution is multivariate the function is called as follows:

3044 `Distribution([dist_name_1,...]).log_pdf(x, [params_1,...])`

3045 In the multivariate case, the output of the **log_pdf** function is the sum of the
3046 marginal **log_pdfs**

$$\sum_i \text{Distribution}(\text{dist_name_i}).\text{log_pdf}(x[:, i], \text{params_i})$$

3047 Here, `x` is a *numpy array* and `params/params_i` is given as a *list*.

3048 • **fit:**

3049 A function that fits the parameters of the specified distribution to user-

3050 specified data *x*.

3051 For a univariate distribution the function is called as follows:

3052 `Distribution(dist_name).fit(x,params)`

3053 If the distribution is multivariate the function is called as follows:

3054 `Distribution([dist_name_1,...]).fit(x, [params_1,...])`

3055 In the multivariate case the output is a *list* with entries the values of

3056 `fit` calculated at *x* for every distribution model defined in `[dist_name_1,`

3057 `dist_name_2,...]`.

3058 Here, *x* is a *numpy array* and `params/params_i` is given as a *list*.

3059 • **moments:**

3060 A function that returns the mean, variance, skewness, and kurtosis, of a speci-

3061 fied distribution. Note that the parameters of the distribution must be passed

3062 into the `moments` function.

3063 For a univariate distribution the function is called as follows:

3064 `Distribution(dist_name).moments(params)`

3065 If the distribution is multivariate the function is called as follows:

3066 `Distribution([dist_name_1,...]).moments([params_1,...])`

3067 In the multivariate case the output is a *list* with entries the values

3068 of `moments` calculated at *x* for every distribution model defined in

3069 `[dist_name_1,dist_name_2,...]`.

3070 Here, `params/params_i` is given as a *list*.

3071 *Supported Distributions*

3072

3073 Table 3 lists the distributions that are currently available in the

3074 `SubDistributions` class.

3075 6.1.3 `UQpy.Distributions.Copula`

3076 The `Copula` class has the following attributes:

Available Distributions in UQpy		
Distribution	Name	Parameters
Beta	“beta”	$[a, b]$ $a, b > 0, (a < b) \in \mathbb{R}$ Fixed: $loc = 0, scale = 1$
Binomial	“binomial”	$[n, p]$ $n \in \mathbb{N}_0, p \in [0, 1]$
Cauchy	“cauchy”	$[loc, scale]$ $loc, scale > 0$
Chi-Squared	“chisquare”	$[df, loc, scale]$
Exponential	“exponential”	$[loc, scale]$
Gamma	“gamma”	$[a, loc, scale]$ $a > 0$
Generalized Extreme Value	“genextreme”	$[c, loc, scale]$
Inverse Gaussian	“inv_gauss”	$[\mu, loc, scale]$
Laplace	“laplace”	$[loc, scale]$ $scale > 0$
Levy	“levy”	$[loc, scale]$ $scale > 0$
Logistic	“logistic”	$[loc, scale]$ $scale > 0$
Lognormal	“lognormal”	$[\sigma, loc, \mu]$ $s = \sigma, loc = loc,$ $scale = \mu, \sigma > 0$
Maxwell-Boltzmann	“maxwell”	$[loc, scale]$ $scale > 0$
Multivariate Normal	“mvnormal”	$[\mathbf{M}, \mathbf{C}]$ $mean = \mathbf{M}, cov = \mathbf{C}$
Normal (Gaussian)	“normal” or “gaussian”	$[\mu, \sigma]$ $loc = \mu, scale = \sigma$ $\sigma > 0$
Pareto	“pareto”	$[b, loc, scale]$ $b, scale > 0$
Rayleigh	“rayleigh”	$[loc, scale]$ $scale > 0$
Truncated Normal	“truncnorm”	$[a, b, loc, scale]$ $a = (\frac{clip_{low} - \mu}{\sigma}), b = (\frac{clip_{high} - \mu}{\sigma})$ $loc = \mu, scale = \sigma$
Uniform	“uniform”	$[a, b]$ $loc = a, scale = b - a$ $b > a$

Table 3: Available distributions in UQpy

Copulas Class Attribute Definitions			
Attribute	Input/Output	Type	Required
copula_name	Input	<i>string</i>	*
dist_name	Input	<i>list</i>	*

and the following methods:

Copula Class Methods	
Method	Type
pdf	<i>function</i>

The copulas currently available in UQpy are listed in the table below:

Supported Copulas in UQpy	
Name	Parameters
“Gumbel”	$\theta \in [1, +\infty)$

6.1.4 User-defined Distributions

Other distributions can be easily added by defining the appropriate functions in a python script (.py). These functions must be consistent with those listed in the “SubDistribution Class Methods” table above.

Description of a (.py) script for a custom distribution

The user may define custom functions that compute the pdf, cdf, inverse cdf, or log_pdf at a specified value for the distribution as well as functions to generate samples, fit distribution parameters, and return the moments of the distribution. These functions should be defined within a single python script (.py). For compatibility with UQpy, the name of each function, must be specified as pdf, cdf, icdf, log_pdf, fit or moments in accordance with the conventions of the SubDistribution class. Each function is required to take inputs as prescribed above in the list of *Distribution Methods* for the SubDistribution class.

6.1.5 Example

An example illustrating the use of the Distribution class is provided in the Jupyter notebook Distributions.ipynb. In this script, example show how to use the Distribution class for:

- A univariate distribution that is included in the supported distributions in Table 3. In this case, we illustrate the use of a lognormal distribution.

- 3103 • A custom bivariate distribution – the Rosenbrock distribution. The func-
3104 tions are provided in the included `rosenbrock.py` file.
- 3105 • A multivariate distribution with independent random variables – specif-
3106 ically, two random variables having a normal and lognormal distribution
3107 respectively.
- 3108 • A multivariate distribution with copula dependence – specifically, a bi-
3109 variate normal distribution with Gumbel copula.

3110 6.2 Utilities Module

3111 The **Utilities** module contains functionality for all the supporting methods
3112 in **UQpy**. It is imported in a python script using the following command:

```
3113     from UQpy import Utilities
```

3114 The **Utilities** module consists of various **functions**, each used for different
3115 purposes and can be called as:

```
3116     from UQpy.Utilities import function
```

3117 A list of the available functions that can be found in **Utilities** with a short
3118 description and the class in which is used is presented next.

3119

List of available functions in module Utilities	
Name	Description
transform_ng_to_g	Transform non-Gaussian to Gaussian rvs
transform_g_to_ng	Transform Gaussian to non-Gaussian rvs
itam	Iterative Translation Approximation Method
run_corr	Correlates standard normal variables
run_decorr	Decorrelates standard normal variables
correlation_distortion	Evaluate the modified correlation matrix
bi_variate_normal_pdf	Evaluate the values of the bi-variate normal pdf
_get_a_plus	A supporting function for the nearest_pd function
_get_ps	A supporting function for the nearest_pd function
_get_pu	A supporting function for the nearest_pd function
nearest_psd	Compute the nearest positive semi definite matrix
nearest_pd	Find the nearest positive-definite matrix
estimate_psd	Estimate the Power Spectrum given an ensemble of samples
s_to_r	Transform the power spectrum to an autocorrelation function
r_to_s	Transform the autocorrelation function to a power spectrum
is_pd	Returns true when input is positive-definite.
resample	Resample a set of samples according to their associated weight
diagnostics	Perform some diagnostics on outputs of MCMC and IS

3121 6.2.1 diagnostics

3122 Diagnostics can help the user in understanding if enough (weighted) samples
3123 were drawn in order to obtain an acceptable approximation of the target distri-
3124 bution using IS or MCMC. The function **diagnostics** takes as parameters the

(weighted) samples, then computes and prints a few diagnostics, in particular the Effective Sample Size (ESS, see explanations and references below). The function will also display a few plots. These diagnostics are mostly qualitative and are meant to provide some guidance for the user in choosing the number of samples required for the approximation, along with some parameters such as the burn-in period and jump parameter in MCMC.

The inputs to the function `diagnostics` are displayed in the following table; most importantly, the user must provide the (weighted) samples as either 1) instances of the MCMC or IS classes in input `sampling_outputs` or 2) `ndarrays` in inputs `samples`, `weights` (if IS). The outputs depend on the sampling method used to obtain the samples (IS or MCMC), and are detailed in the following sections.

diagnostics function inputs		
Input	Type	Comment
<code>sampling_method</code>	<code>str</code>	required, 'IS' or 'MCMC'
<code>sampling_outputs</code>	<code>ndarray</code>	required if <code>samples</code> is None
<code>samples</code>	<code>ndarray</code>	required if <code>sampling_outputs</code> is None
<code>weights</code>	<code>ndarray</code>	required if <code>sampling_method</code> is None and <code>sampling_outputs</code> is 'IS'
<code>figsize</code>	<i>tuple of floats</i>	size of the displayed figure
<code>eps_ESS</code> , <code>alpha_ESS</code>	<i>floats</i>	between 0 and 1, default 0.05, see [8], only used if <code>sampling_method</code> is 'MCMC'

Diagnostics for Importance Sampling

For IS, in extreme settings only a few samples may have a significant weight, yielding very poor approximations of the target pdf $p(x)$. A popular diagnostics is the Effective Sample Size (ESS), which is theoretically defined as the number of independent samples generated directly from the target distribution that are required to obtain an estimator with same variance as the one obtained from IS / MCMC. Heuristically, ESS approximates how many i.i.d. samples, drawn from the target, are equivalent to n weighted samples drawn from the IS or MCMC approximation. An approximation of the ESS is given by [1]:

$$ESS = \frac{1}{\sum \tilde{w}^2}$$

where \tilde{w}^2 are the normalized weights.

3141 The diagnostics function will compute and print the ESS; it will also dis-
 3142 play a plot of the weights, allowing the user to qualitatively assess how many
 3143 samples have a non-negligible weight.

3144 **Diagnostics for MCMC**

3145 In MCMC, the *ESS* has been used to derive termination rules, based
 3146 on the quality of the estimation. In brief, the simulation stops when the
 3147 computational uncertainty on a chosen quantity (in UQpy, this quantity is
 3148 the expected value of RV x) is small compared to its posterior uncertainty
 3149 [8]. Mathematically, this allows computation of the *ESS* and a minimum
 3150 value ESS_{min} (qualitatively, an acceptable approximation is reached if $ESS >$
 3151 ESS_{min}). These quantities can be computed by looking at each marginal
 3152 density (is x is a multivariate random variable), or by looking at the joint.
 3153 The reader is referred to [8, 23] for more details. In UQpy, both the univariate
 3154 *ESS*, ESS_{min} in all dimensions of x and the multivariate version are computed
 3155 and displayed.

3156 The function also displays a plot with $n_x \times 3$ subplots, where n_x is the
 3157 dimension of the RV x . For each dimension (each row of the plot), the first
 3158 column shows a plot of the chain. This allows the user to qualitatively assess
 3159 if the mixing properties of the chain are acceptable, and also if a larger burn-
 3160 in should be used (by looking at the beginning of the chain). The second
 3161 column displays convergence plots, i.e., the evolution of $E[x]$ as more samples
 3162 are drawn, allowing the user to qualitatively assess if the chain has converged.
 3163 Finally, the third column displays plots of the correlation between samples
 3164 (recall than in MCMC, drawn samples are not i.i.d), which can guide the user
 3165 in choosing the jump parameter for MCMC and discarding some samples.

3166 6.2.2 resample

3167 The function **resample** allows to transform a weighted set of samples into an
 3168 unweighted set of samples by eliminating samples with low weight and mul-
 3169 tiplying samples with large weights. Practically, the samples are re-sampled
 3170 with probability equal to their weight. Several resampling strategies exist and
 3171 could lead to better estimations, they will be integrated in future version of
 3172 UQpy.

3173 The user must simply provide the samples as an **ndarray** of dimension
 3174 (nsamples \times dimension) (input **samples**), their associated weights as an
 3175 **ndarray** of dimension (nsamples,) (input **weights**). Optionally, an input
 3176 **size** may be provided, then only **size** samples will be resampled; otherwise
 3177 size is set to nsamples. The output is a set of (unweighted) samples as an
 3178 **ndarray** of dimension (size \times dimension)

3179 7 Adding new classes to UQpy

3180 Adding new capabilities to UQpy is as simple as adding a new class to the
3181 appropriate module and importing the necessary packages into the module.
3182 Further details will be provided in the future as UQpy coding practices are
3183 formally established.
